# Outline

---

- Approach
- Results:
  - DME Interference
  - Link 16 Interference
  - Single UAT + White Gaussian Noise
- Status

# Definition of Signal, Interference & Noise Levels

## (Spectrum Analyzer Settings)

---

- UAT (as desired or interfering signal)
  - Frequency of Peak Level in 5-MHz Span around 981 MHz
    - Tends to occur at UAT mark or space frequency
  - 1 MHz Resolution BW
  - 1 MHz Video BW / Max Hold
- DME
  - Frequency of Peak Level in 5-MHz span around 981 MHz
    - Occurs near DME center frequency
  - 1 MHz Resolution BW
  - 1 MHz Video BW / Max Hold
- Link 16
  - Frequency of Peak Level in 5-MHz Span around Link 16 freq (981, 984, 987, ... 1002 MHz)
  - 3 MHz Resolution BW
  - 3 MHz Video BW / Max Hold
- White Gaussian Noise
  - Frequency of Peak Level in 5-MHz Span around 981 MHz
    - Occurs randomly throughout span
  - 1 MHz Resolution BW
  - 300 Hz Video BW

# *BER Testing Approach*

---

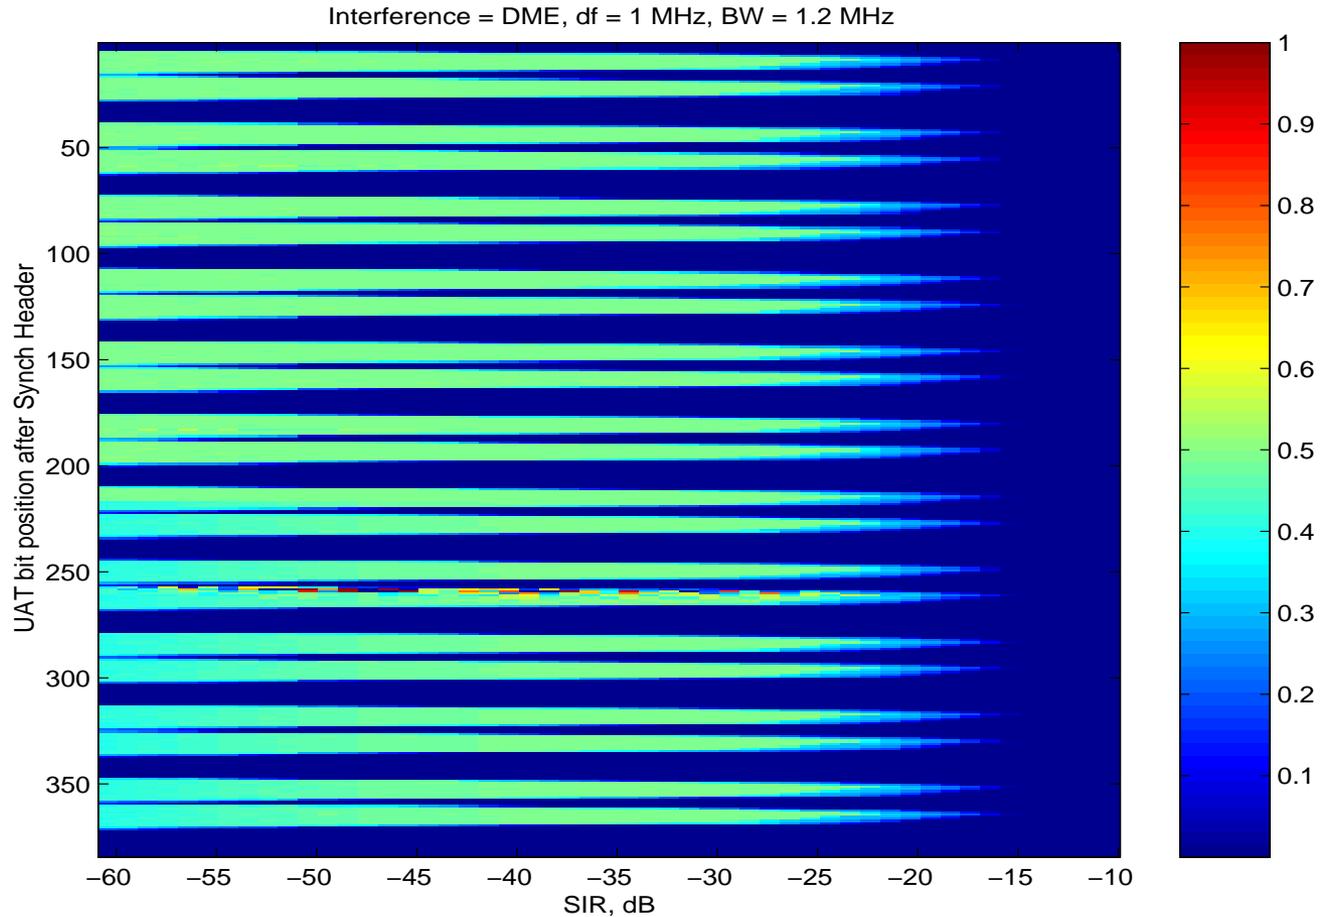

- Desired signal = UAT Long message
- For pulsed (DME and Link 16) interference:
  - Pulse positions held fixed relative to UAT message
    - Specially clocked & gated DME and Link 16 transmitters provided by JSC
  - 5 to 12 interference pulses per UAT message
    - 30 (high SIR) or 15 kHz (low SIR) DME rate
    - 38 kHz Link 16 rate (every other hop)
  - No interference pulses during UAT synch header
  - Approx. 60,000 pulses measured for each SIR, interference type, and frequency offset
- BER computed separately for each of 384 payload/FEC bit positions
  - Reported TX and RX messages were compared bit-by-bit, regardless of whether or not they decoded
- Interference level fixed at  $\sim -40$  dBm or  $-20$  dBm while UAT signal level varied

# Difficulties Encountered In Measuring Bit Errors

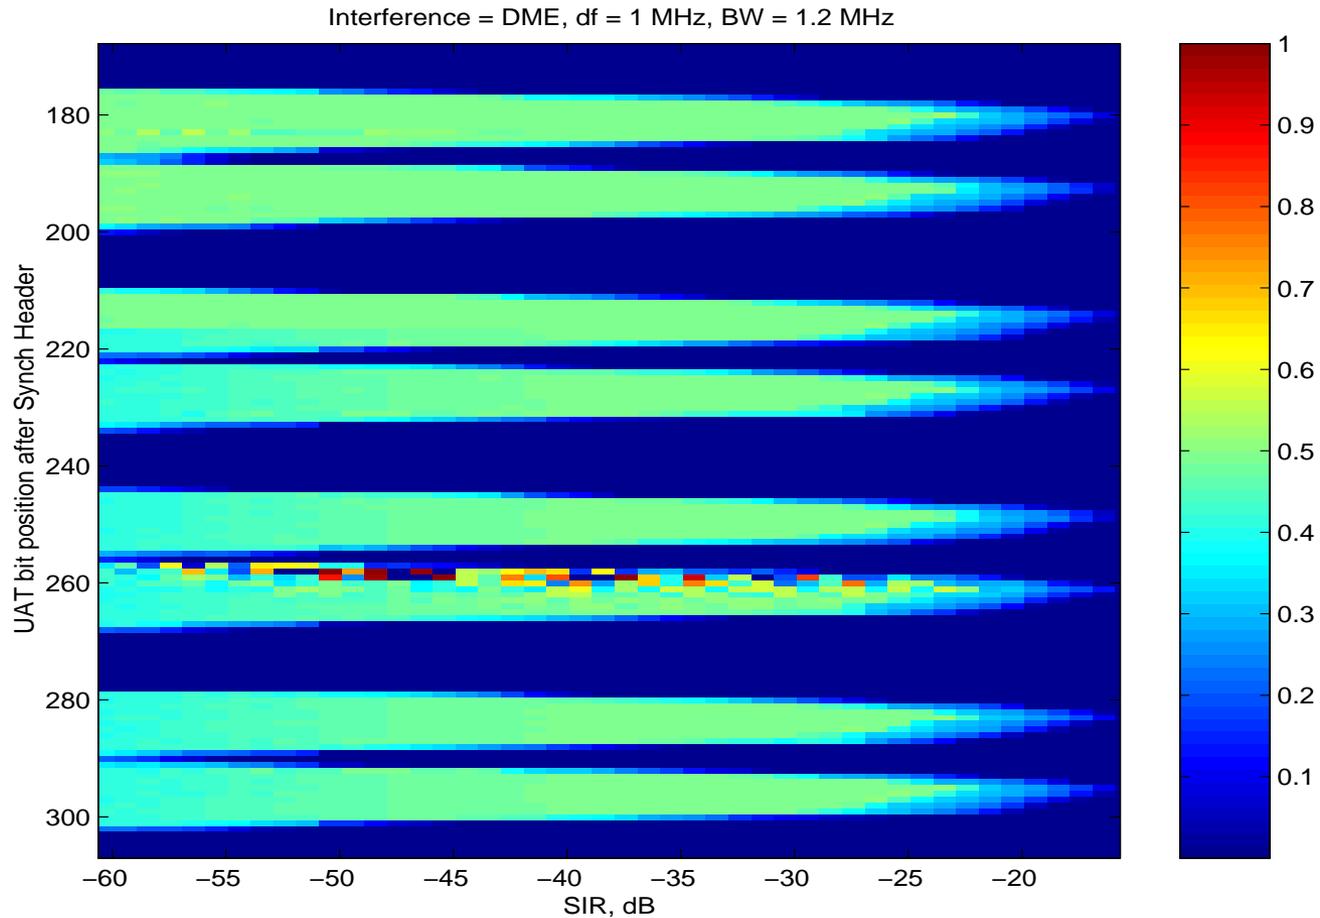

---

- Non-random bits in message Sequence Number (bits 257-272) gave variable results
  - Most slowly changing bits (257-260) showed largest effect
  - Could be due to asymmetric bit error probabilities (0-to-1 vice 1-to-0)
    - e.g. unequal probabilities for sent bit, plus off-frequency interference
  - Modified pseudo-random data generation to make all bits change fast
    - But didn't use on DME or Link 16 tests
      - Wanted to minimize change to JSC MER test setup
- Raw bit data reported by TX and RX units was not always reliable
  - Both TX and RX units occasionally reported spurious raw messages
  - RX units occasionally reported (or we caused) raw messages with bytes shifted left one or more positions
  - Work-around was to reject any report of received message with >30% average BER over last 21 bytes

# Sample Raw BER Data For A Single Interference Type-- Each vertical slice shows BER (color) measured at a single SIR value

# Detail of Raw BER Plot, showing bad data at bits 257-260+, and impact of rejecting reports with high BER over last 21 bytes (bits 217+)

# Post-Measurement Processing

---

- Average together all pulses (or pulse pairs) within a message
  - Align them in time with one another
    - Non-integer bit offsets
  - Average all samples within +/- 0.5 bit
    - For positions spaced every 0.5 bit
- Procedures for handling data anomalies
  - Non-random Sequence Number bits
    - Remove bits 257-260 from averages
  - Data in bits 217-384 biased low by rejecting bad reports
    - Data renormalized upward by fixed multiplier determined as best fit
- Receiver noise subtraction
  - For very low SIRs, excess bit errors due to receiver noise ( $BER_N$ , computed from average BER when no pulse was present) were subtracted as  $BER_I = (BER_{I+N} - BER_N) / (1 - 2 * BER_N)$
  - Enabled BER estimation down to -95 dBm

---

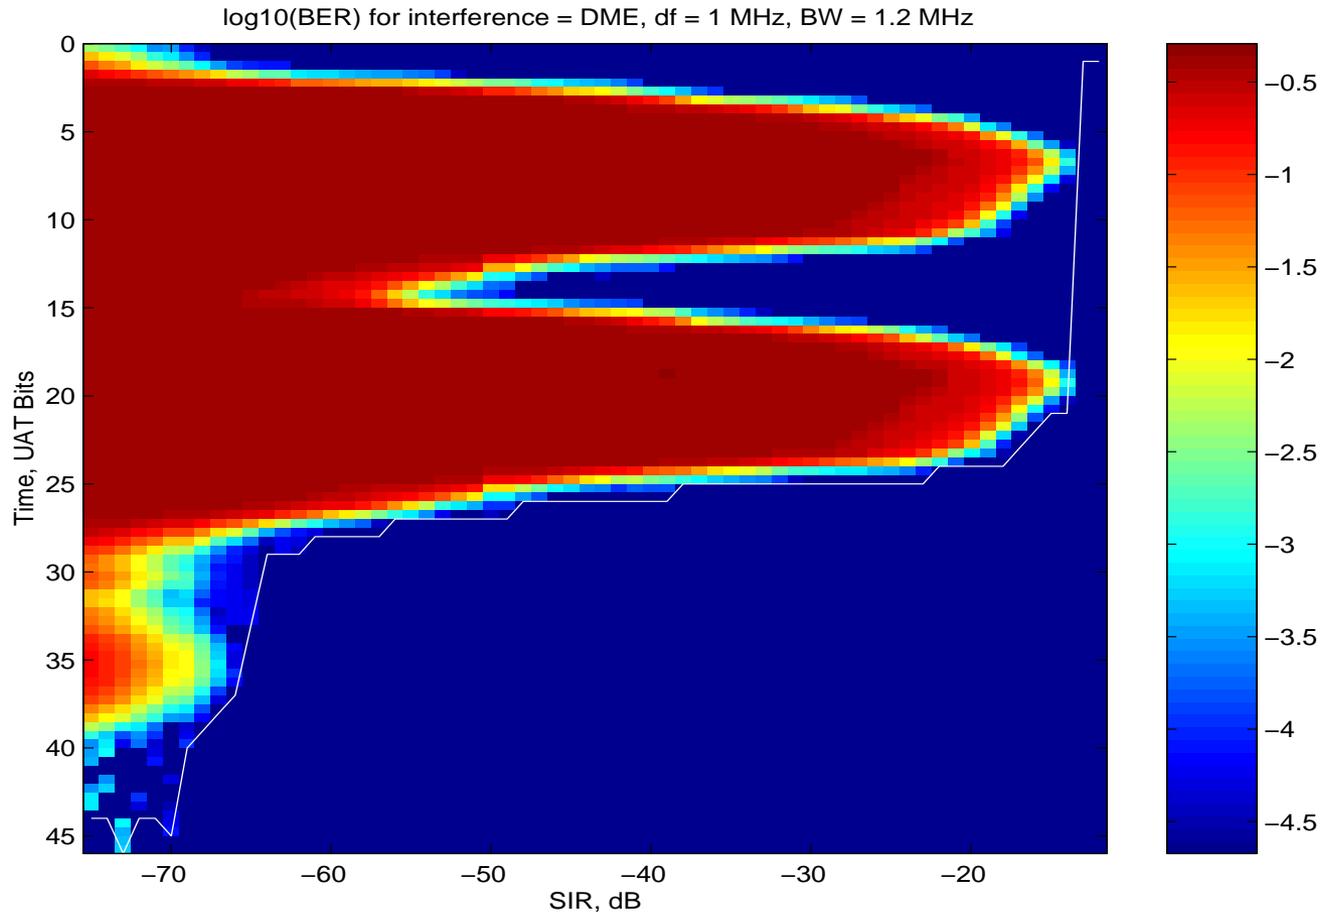

***Interference = DME***

---

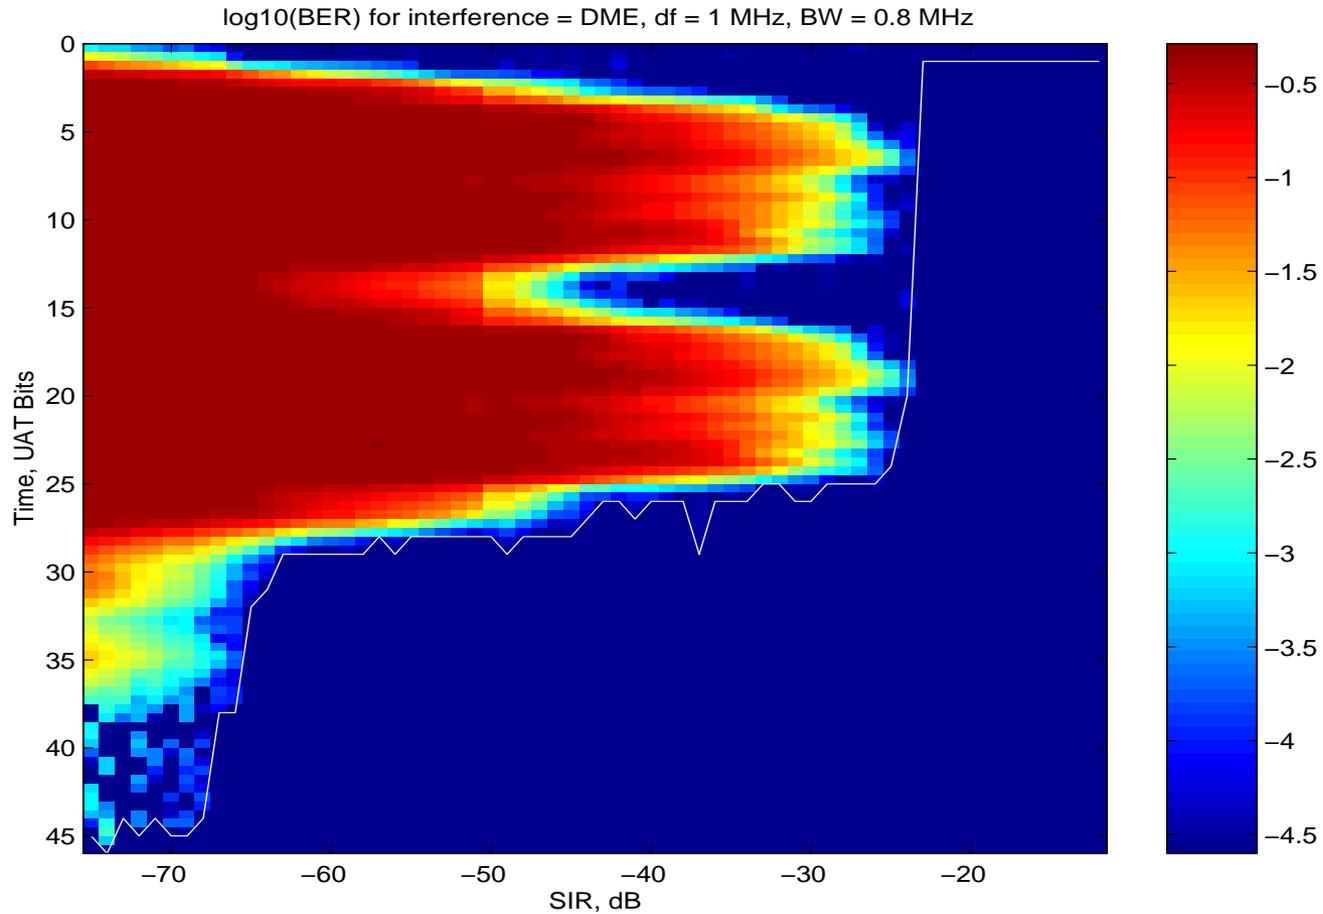

## *Summary Plots for DME Interference (BER Vs. Time & SIR)*

- Summarizes all measured DME data
  - For each  $\Delta\text{freq}$  (0 for On-channel, 1 for Adjacent-channel)
  - For each Bw (0.8 or 1.2 MHz)
  - Averaged over all interference pulses within a UAT message
- $\log_{10}$  {BER} encoded as color

# DME Interference, $\Delta\text{freq} = 1 \text{ MHz}$ $B_w = 1.2 \text{ MHz}$

# DME Interference, $\Delta\text{freq} = 1 \text{ MHz}$ $Bw = 0.8 \text{ MHz}$

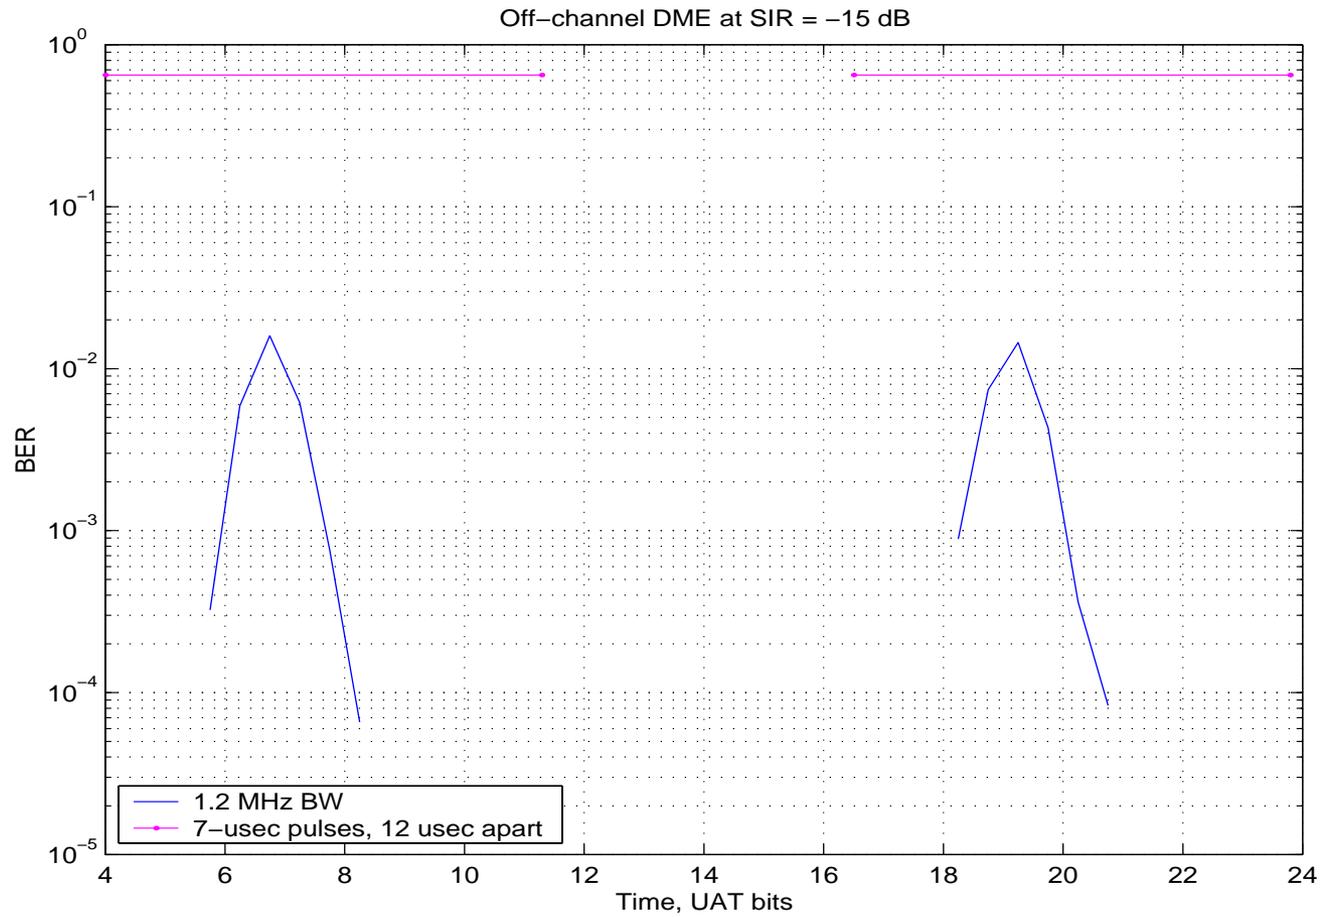

---

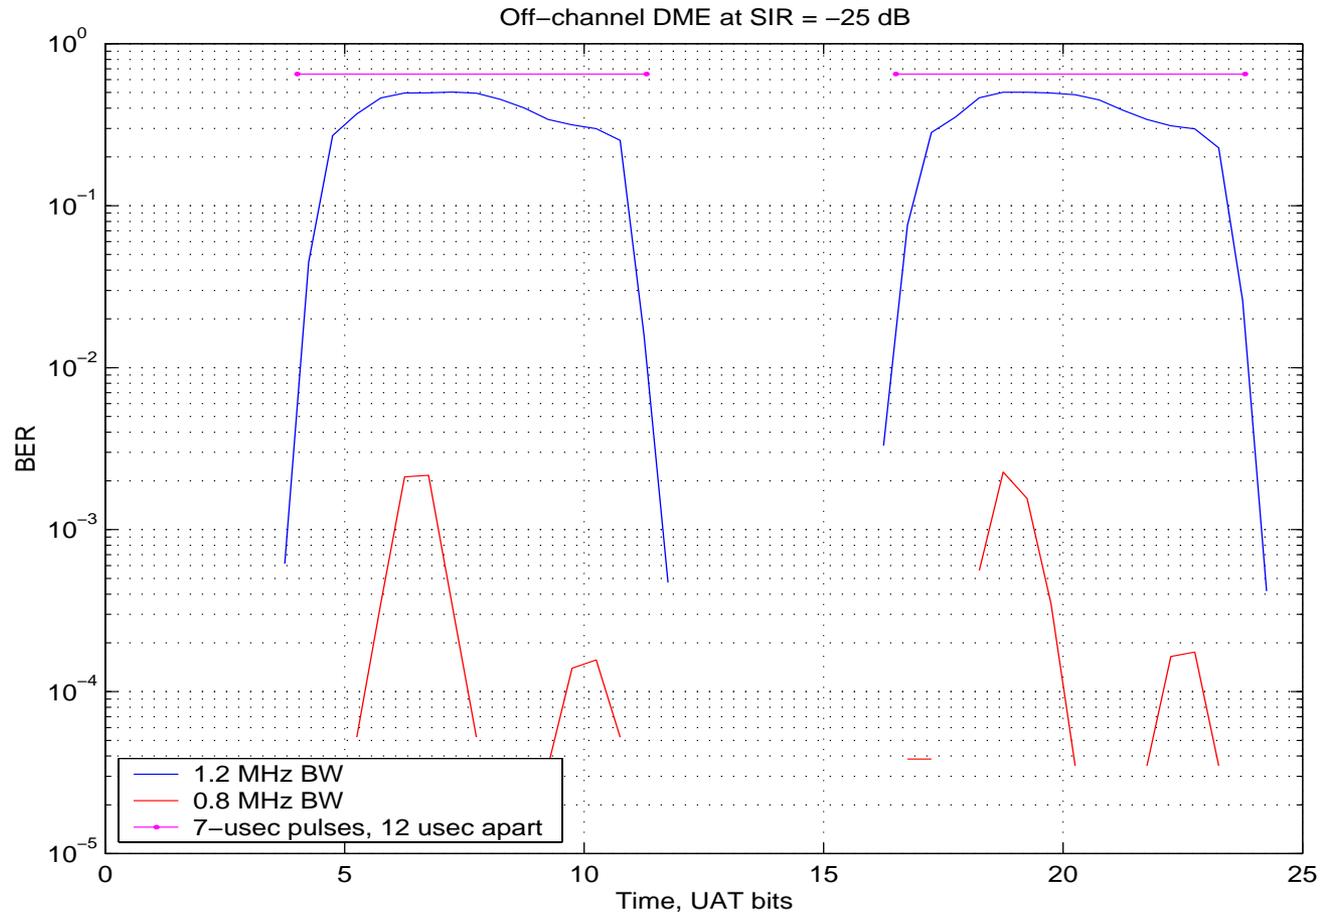

## *BER Vs. Time Plots for DME Interference*

- Vertical slice through color plot at selected fixed values of SIR
- For adjacent-channel DME only
- Compares 1.2 MHz and 0.8 MHz BWs

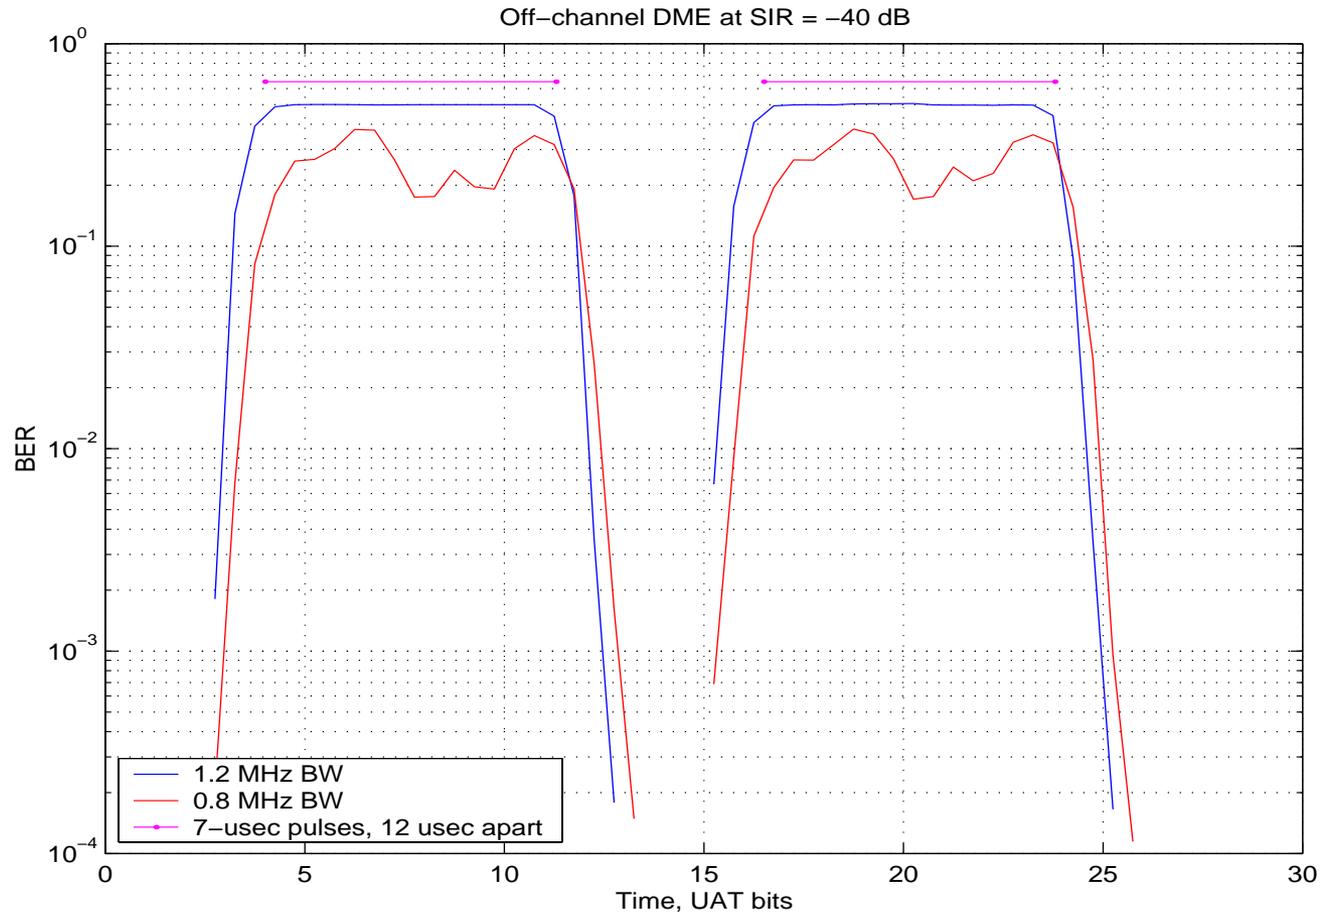

# $SIR = -15 \text{ dB}$

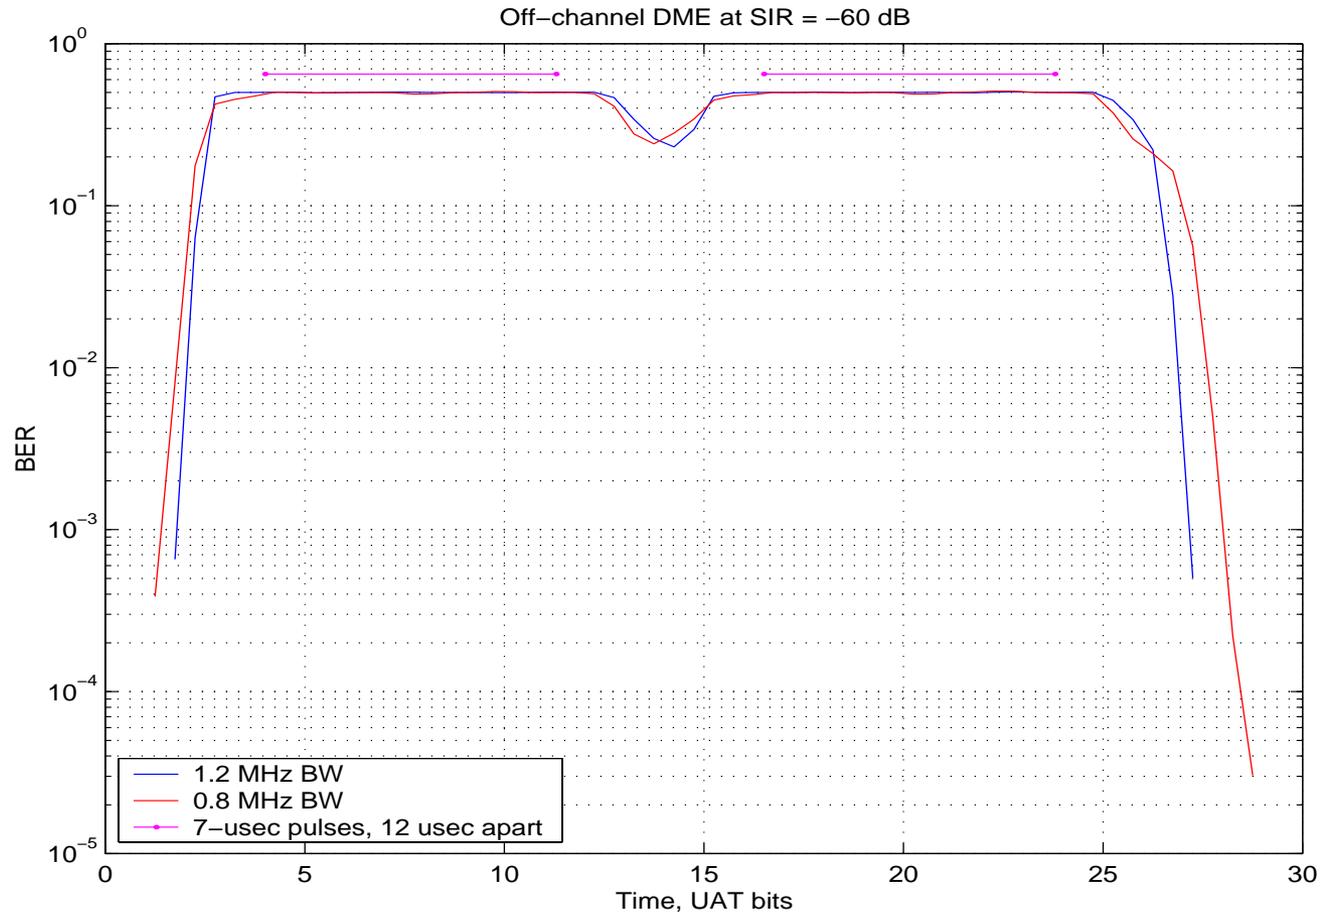

# SIR = -25 dB

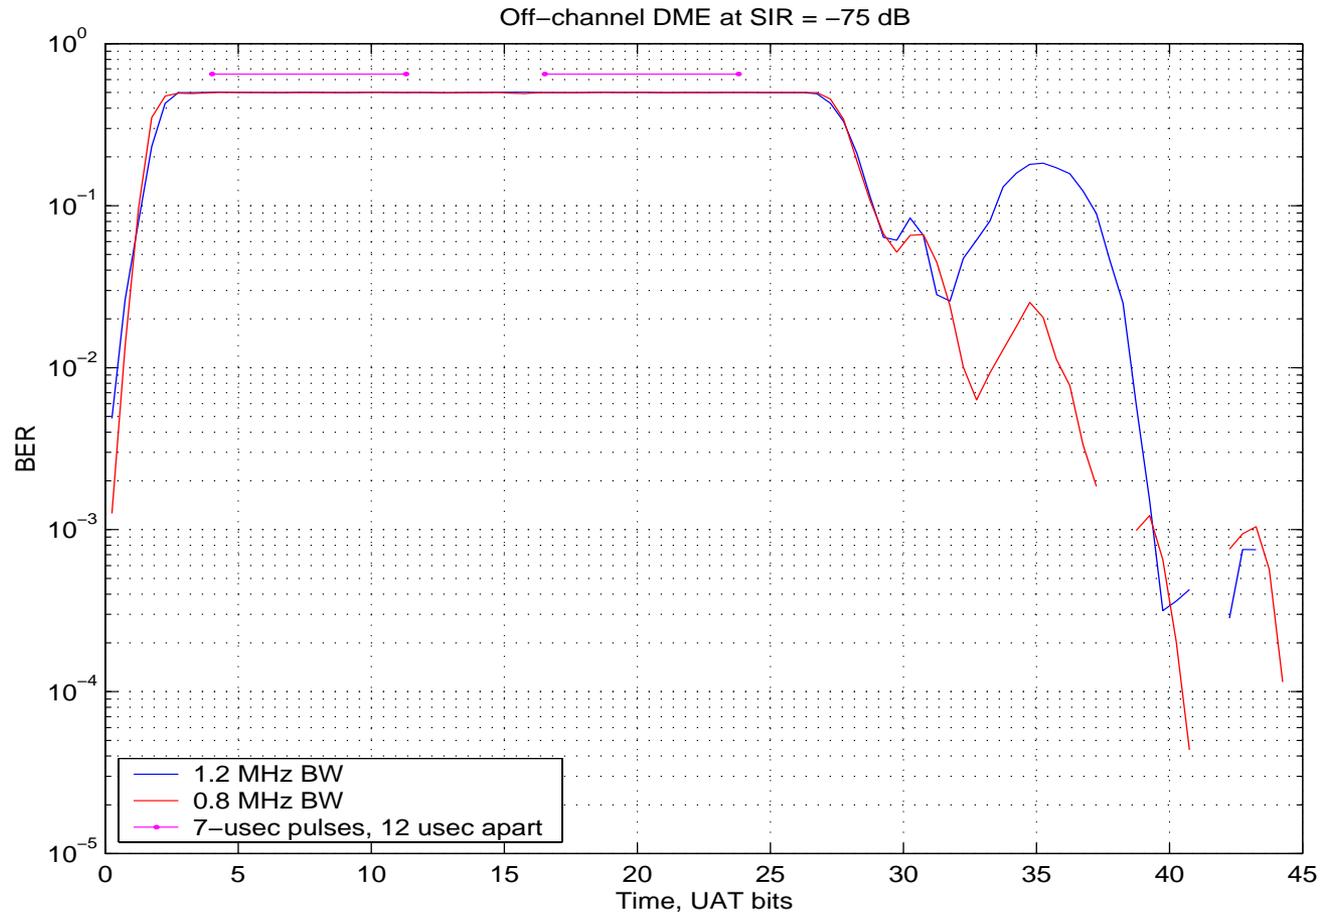

# SIR = -40 dB

# $SIR = -60 \text{ dB}$

# SIR = -75 dB

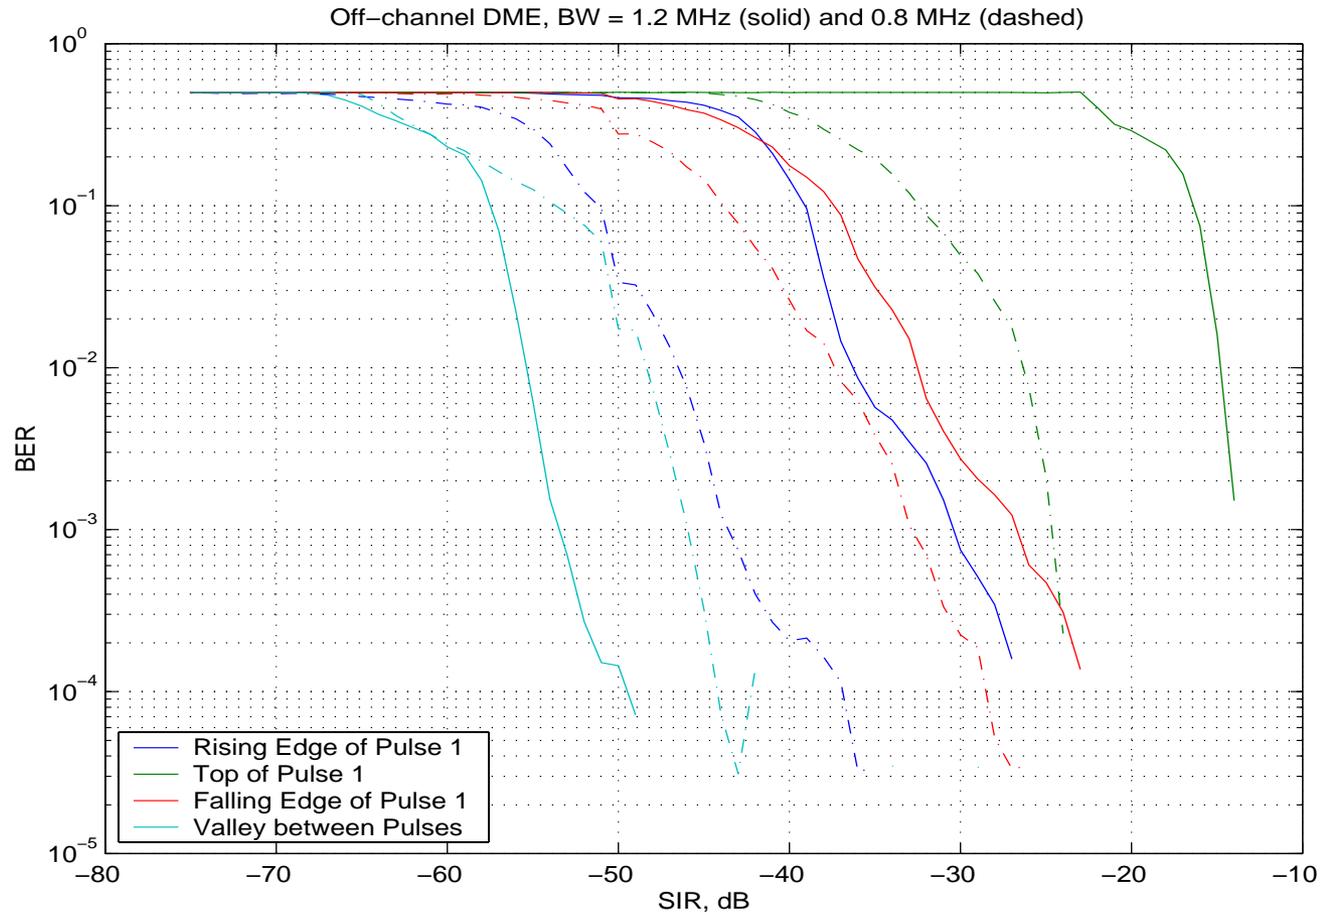

---

## *BER Vs. SIR Plot for DME Interference*

(Horizontal slice through color plot at selected time values)

# Off-Channel DME

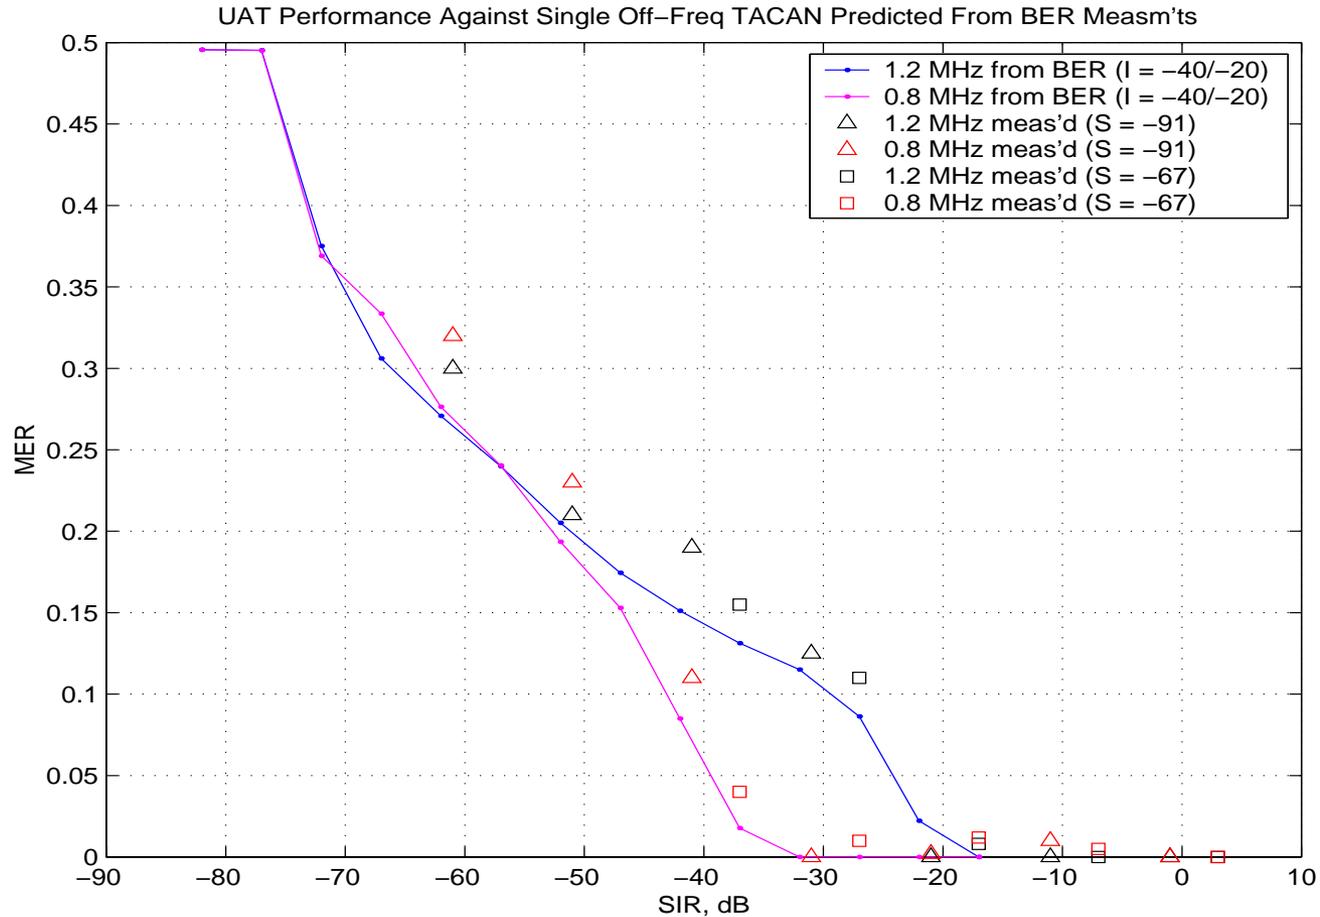

# *Comparison of UAT MER & BER Test Results Against DME*

---

- Approach:
  - Computer simulation converts BER test results into MER predictions
  - These MER predictions are compared with MITRE/JSC-measured MER
- Simulated/measured scenario:
  - DME
    - Single DME transponder
    - 3600 pulse-pairs/second (TACAN), 60-usec+Poisson timing statistics
    - Adjacent-channel (1 MHz away)
  - “Pre-MOPS” UAT
    - 0.8 or 1.2 MHz bandwidth
    - RS(48,34) coding
- Results:
  - BER-based model predicts MER 3-5% (or 4-5 dB) lower than measured
  - Bad MER computation? Bad BER, MER or SIR measurements?

# Measured Vs. BER-Predicted MER

## Single Adjacent-Channel DME @ 3600 pulse pairs/sec

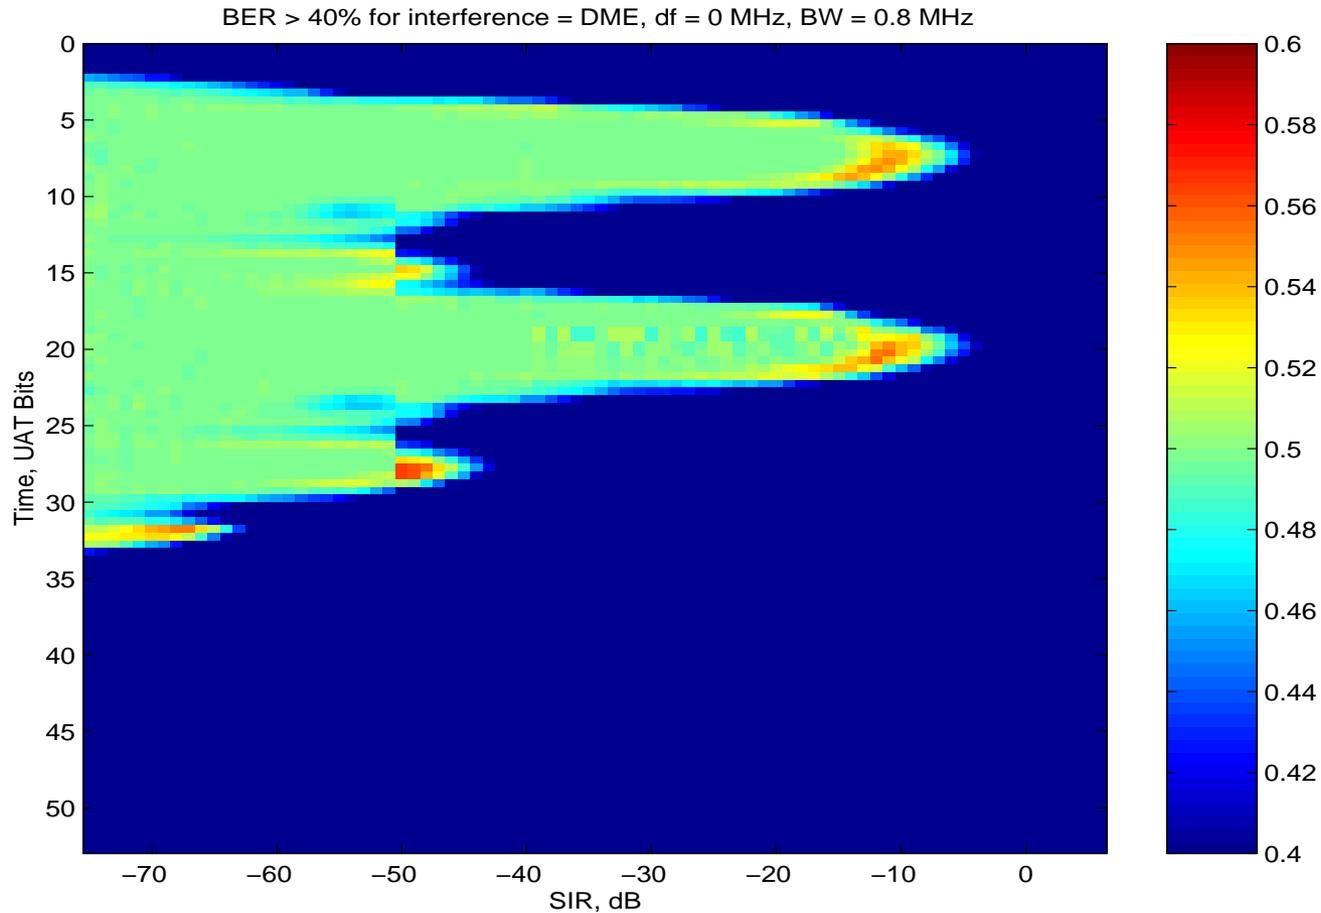

# *BER Observations for DME Interference*

---

- 0.8 MHz filter doesn't provide hoped-for 20 dB improvement over 1.2 MHz filter for Adjacent-channel DME
  - Agrees with MER measurements
- Significant “pulse stretching” occurs at very low SIR values
  - In part due to what looks like a ~7.5-usec echo, down ~ 40 dB
- BER vs. SIR curves are not parallel
  - Can't properly model using simple Pulse amplitude vs. Time profile
  - Could be due to dynamic response of demodulator thresholding algorithm
- BERs above 50% were measured under certain conditions
  - Up to ~ 56%
  - Appear real rather than experimental error
    - Might be due to nonlinear thresholding algorithm in demodulation
  - Would not affect network performance simulations

# *BER > 50% Measured in some cases*

*(e.g. DME Interference,  $\Delta\text{freq} = 0$  MHz,  $BW = 0.8$  MHz)*

# Other Observations

---

- Reed Solomon decoder appears to behave as modeled
  - In 100,000 messages looked at:
    - No messages were incorrectly decoded
    - All messages with  $\leq 7$  byte errors were decoded
    - No messages with  $> 7$  byte errors were decoded
- BER Correlation analysis
  - Correlation of successive bit errors not yet analyzed
  - No significant correlation seen between DME pulse rising and falling edges
    - This result supports measured pulse stretching as real rather than time jitter in experimental setup
      - Time jitter would produce negative correlation

---

***Interference = Link 16***

---

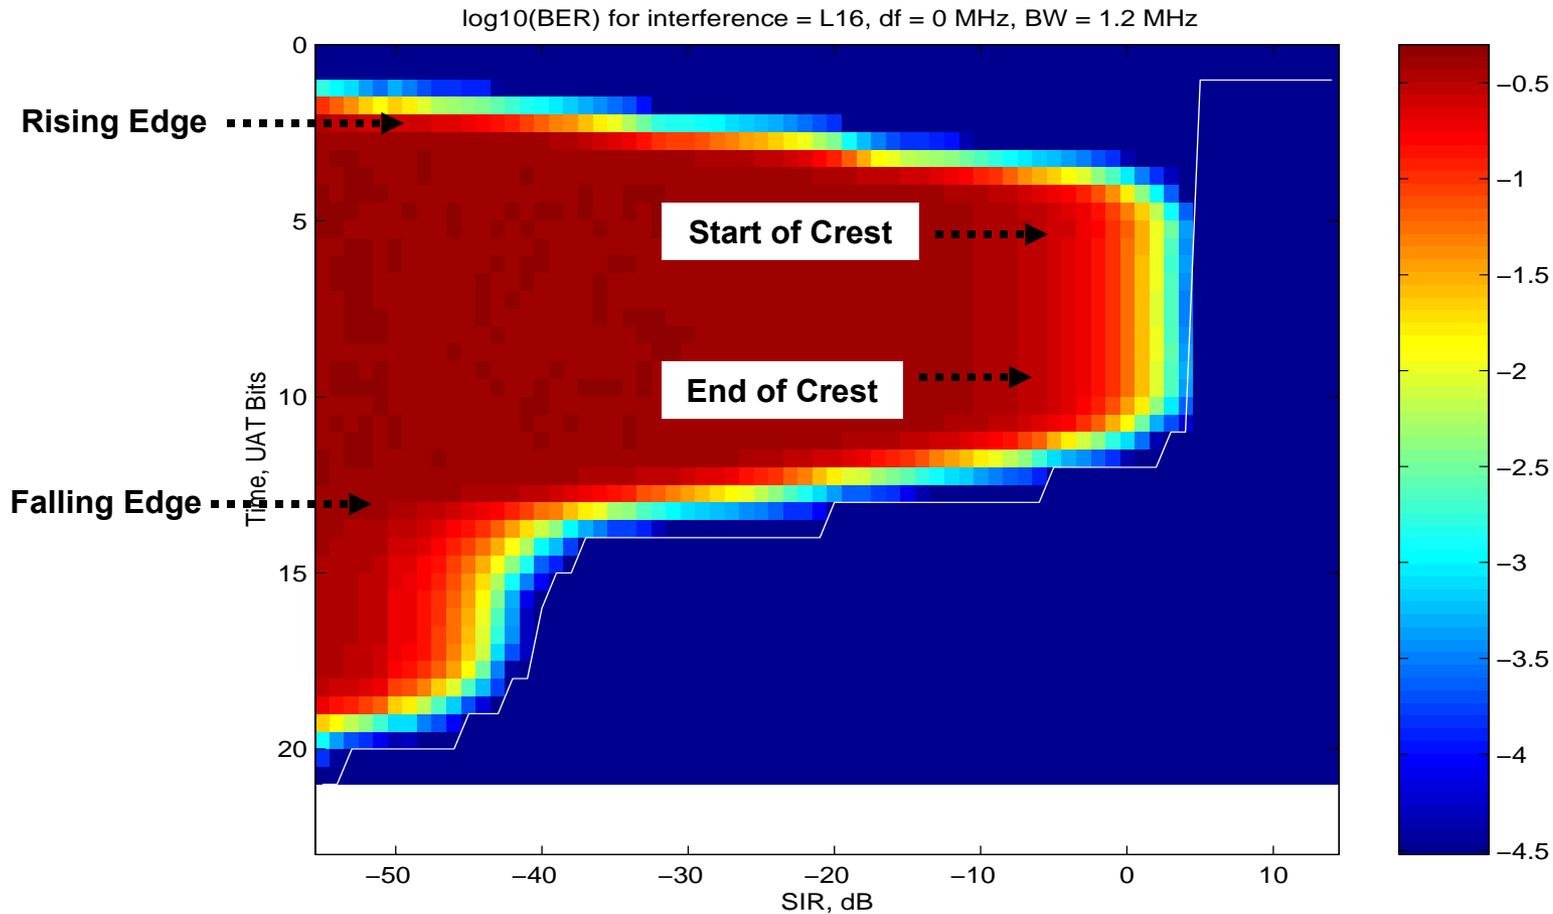

## *Summary Plots for Link 16 Interference (BER Vs. Time & SIR)*

- Summarizes all measured Link 16 data
  - For each  $\Delta\text{freq}$  (0, 3, 6, ... 21 MHz)
  - For each Bw (0.8 or 1.2 MHz)
  - Averaged over all interference pulses within a UAT message
- $\log_{10}$  {BER} encoded as color

# Link 16 Interference, $\Delta\text{freq} = 0$ MHz

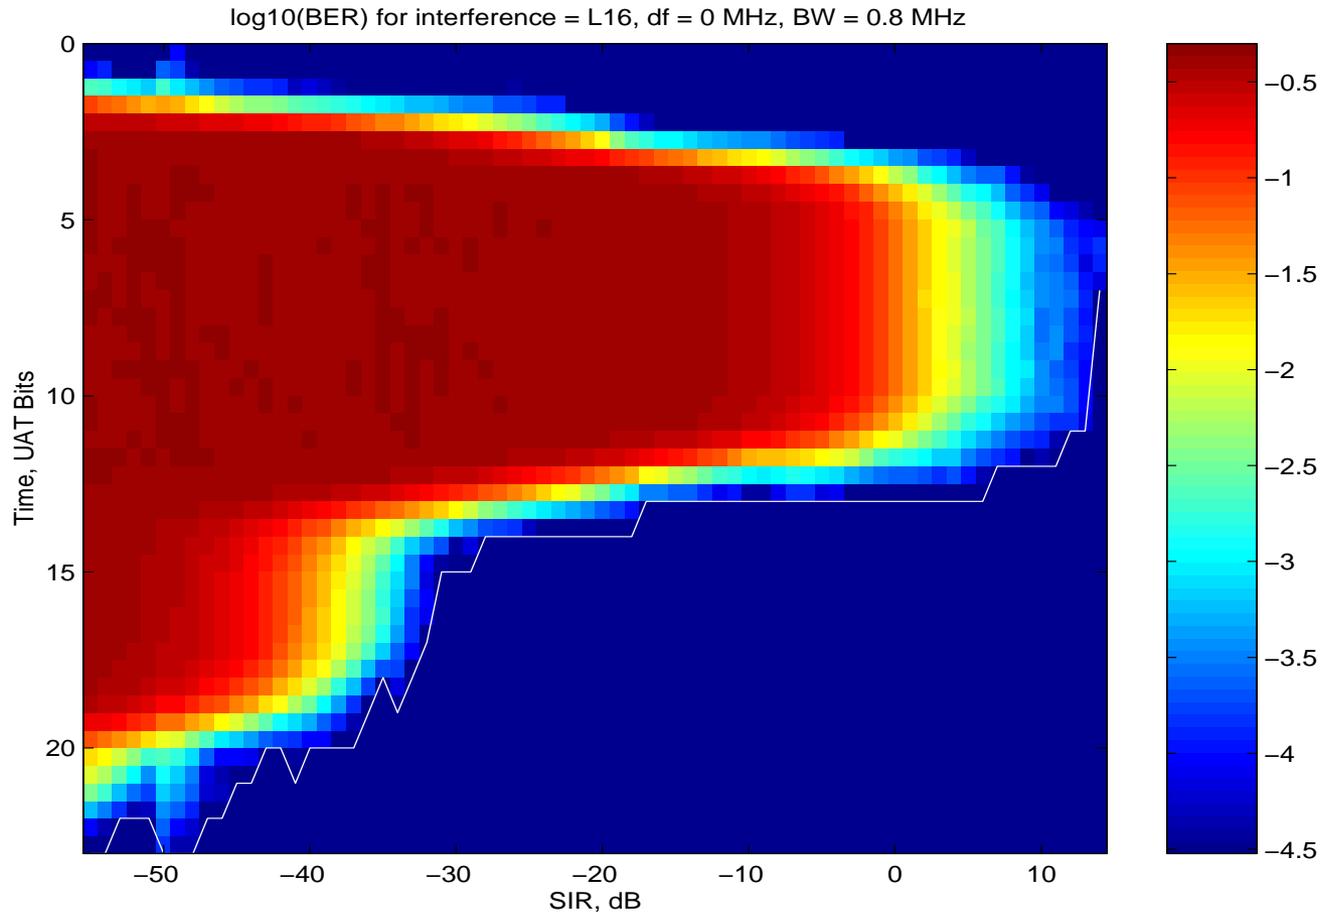

## $B_w = 1.2$ MHz

(including time definitions used in later plots)

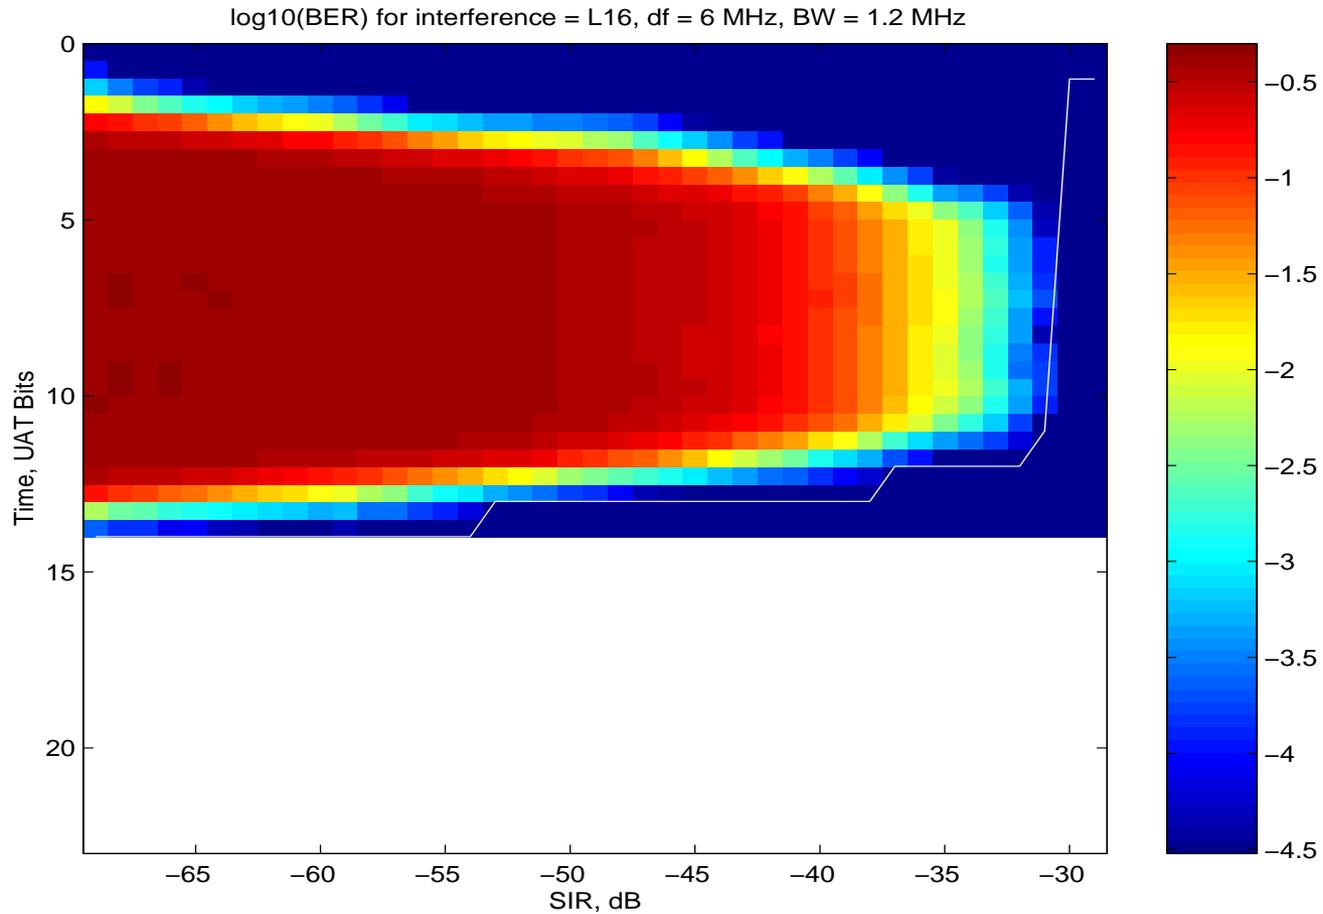

# Link 16 Interference, $\Delta\text{freq} = 0$ MHz

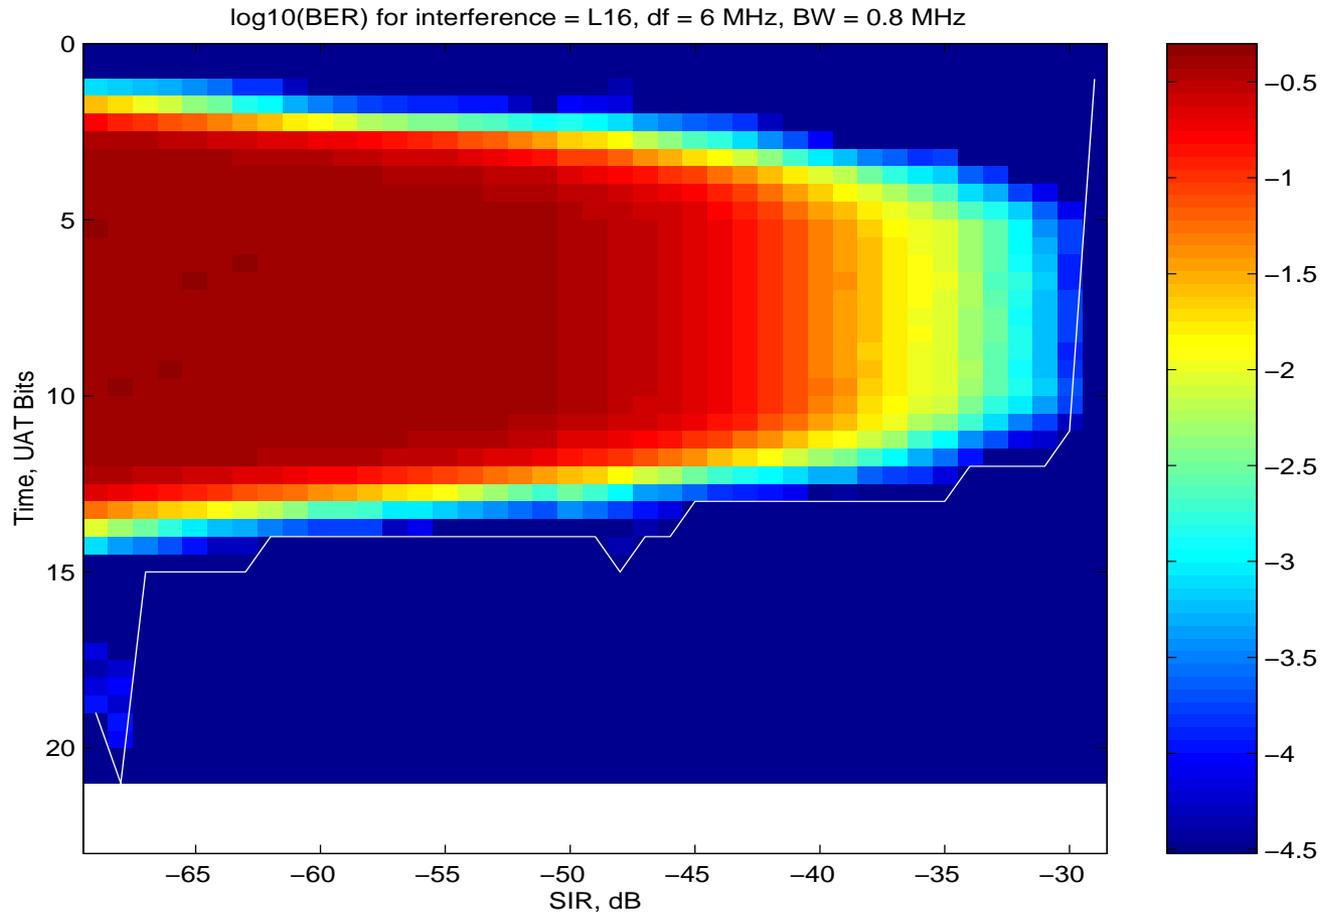

## $B_w = 0.8$ MHz

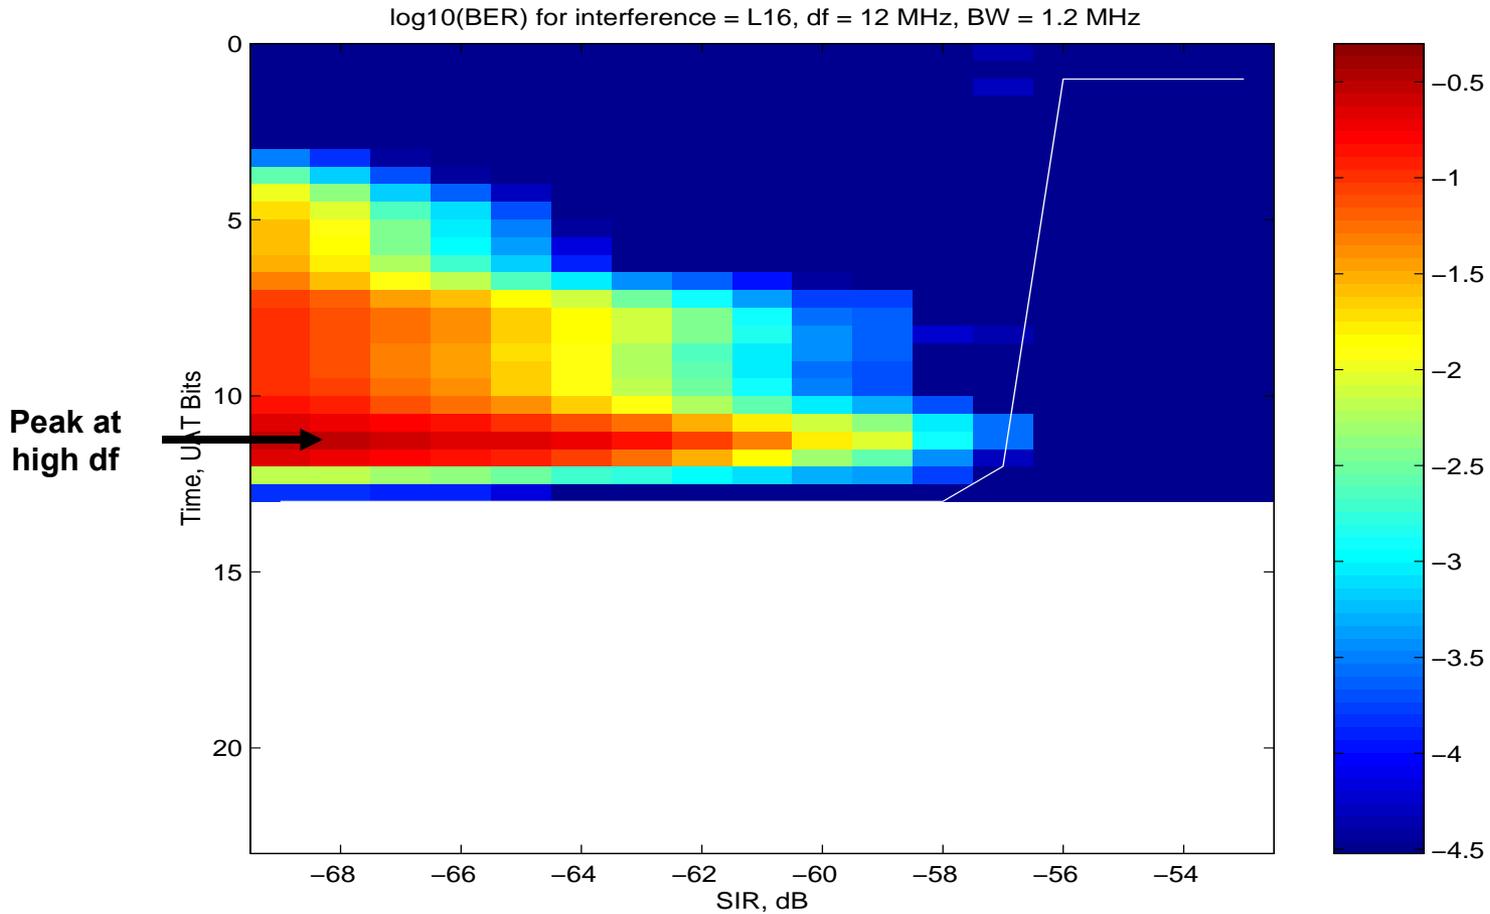

# Link 16 Interference, $\Delta\text{freq} = 6\text{ MHz}$ $B_w = 1.2\text{ MHz}$

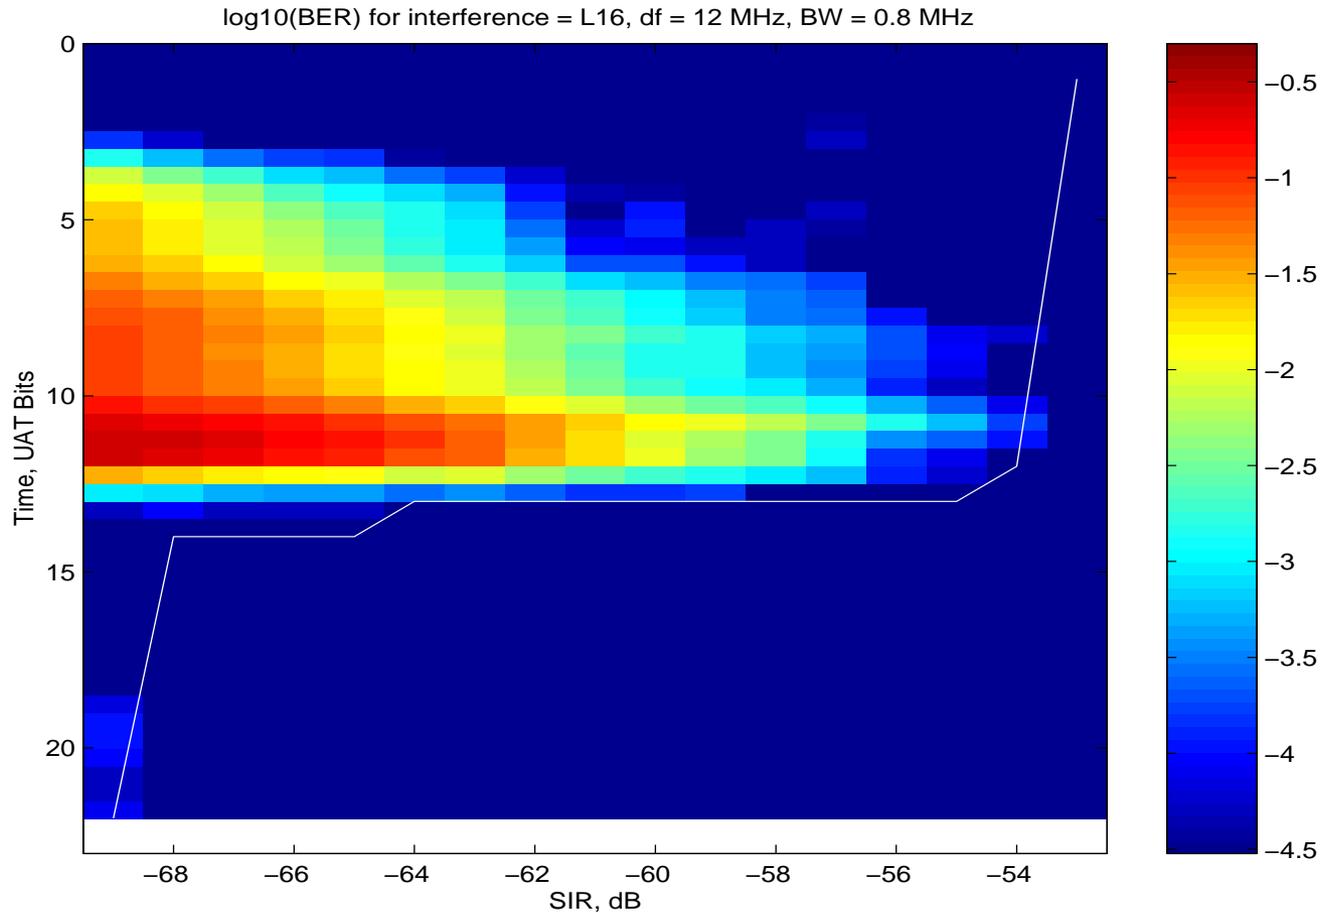

# Link 16 Interference, $\Delta\text{freq} = 6\text{ MHz}$ $B_w = 0.8\text{ MHz}$

# Link 16 Interference, $\Delta\text{freq} = 12\text{ MHz}$ $B_w = 1.2\text{ MHz}$

# Link 16 Interference, $\Delta\text{freq} = 12\text{ MHz}$ $Bw = 0.8\text{ MHz}$

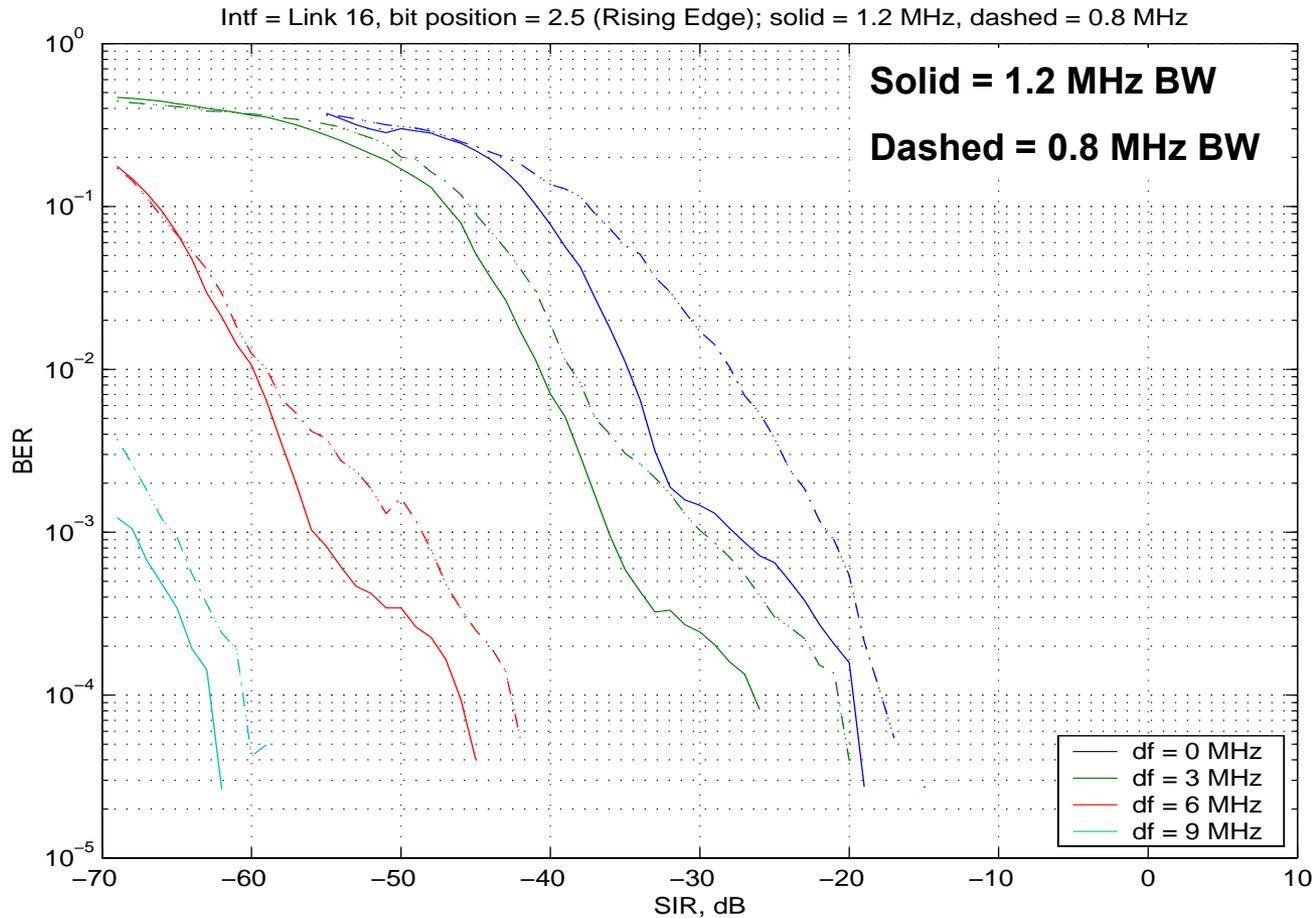

---

## *BER Vs. SIR Plots for Link 16 Interference*

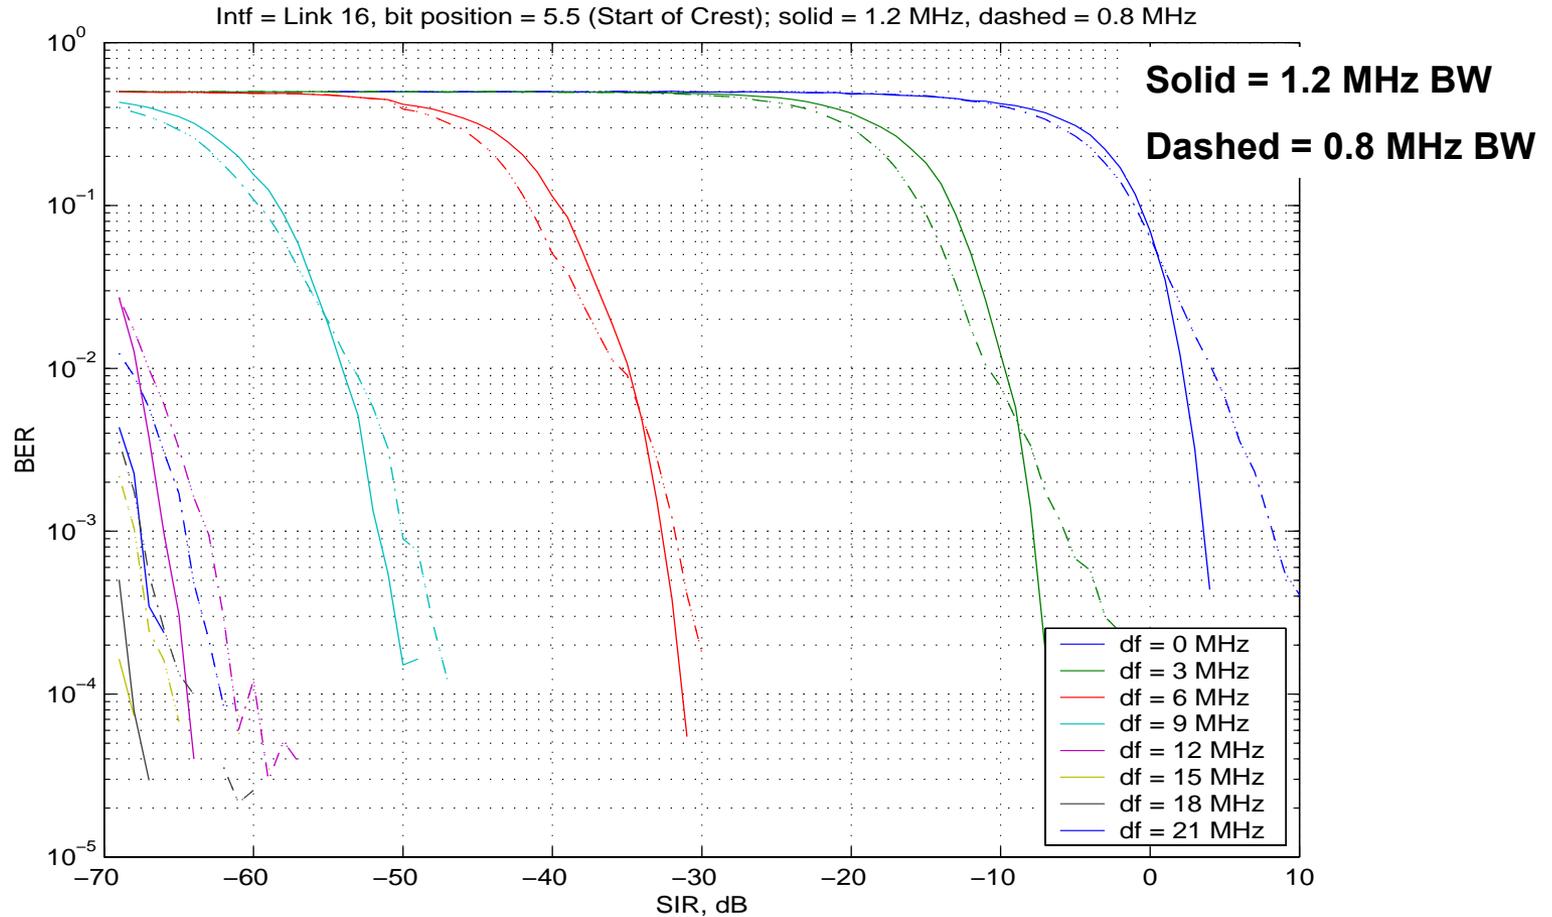

(Horizontal slice through color plot at selected time values)

# Bit Position 2.5 (Rising Edge of Link 16)

for various frequency offsets and receiver BWs

# Bit Position 5.5 (Start of Link 16 Crest) for various frequency offsets and receiver BWs

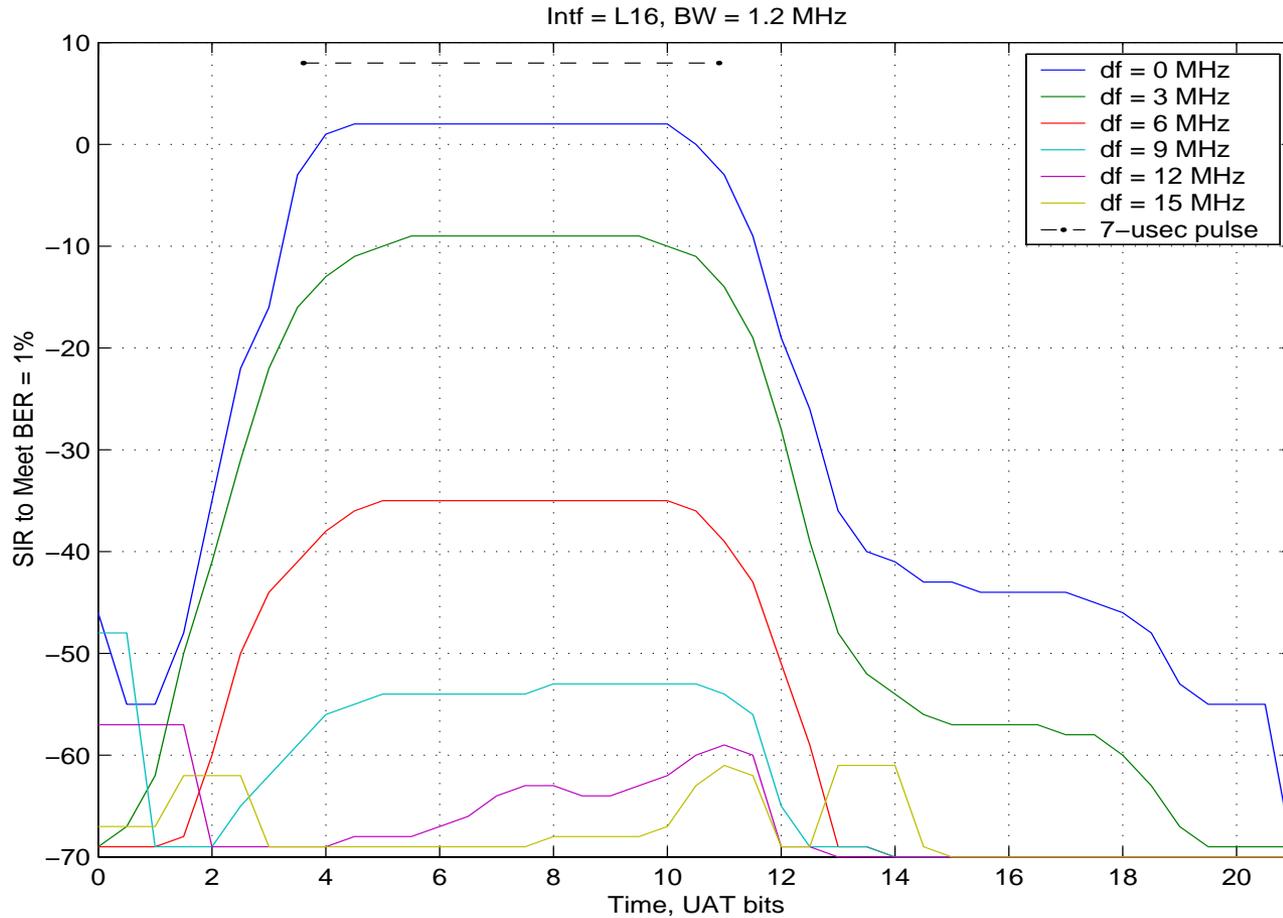

---

## *Required SIR Vs. Time Plots for Link 16 Interference*

(SIR required to meet BER  $\leq 1\%$  at various  
frequency offsets)

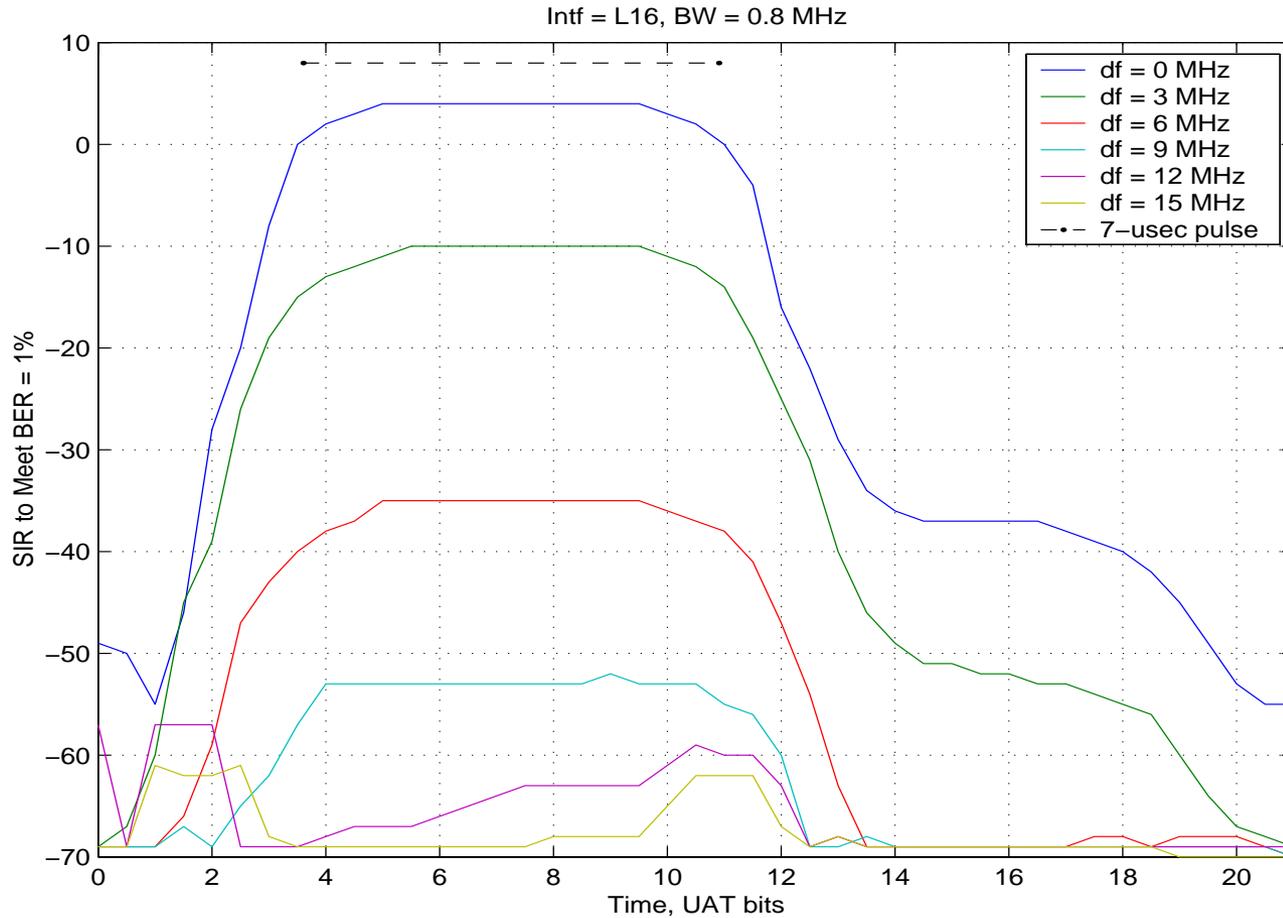

# *SIR Required to Meet BER $\leq 1\%$*

## *BW = 1.2 MHz*

# *SIR Required to Meet BER $\leq 1\%$*

## *BW = 0.8 MHz*

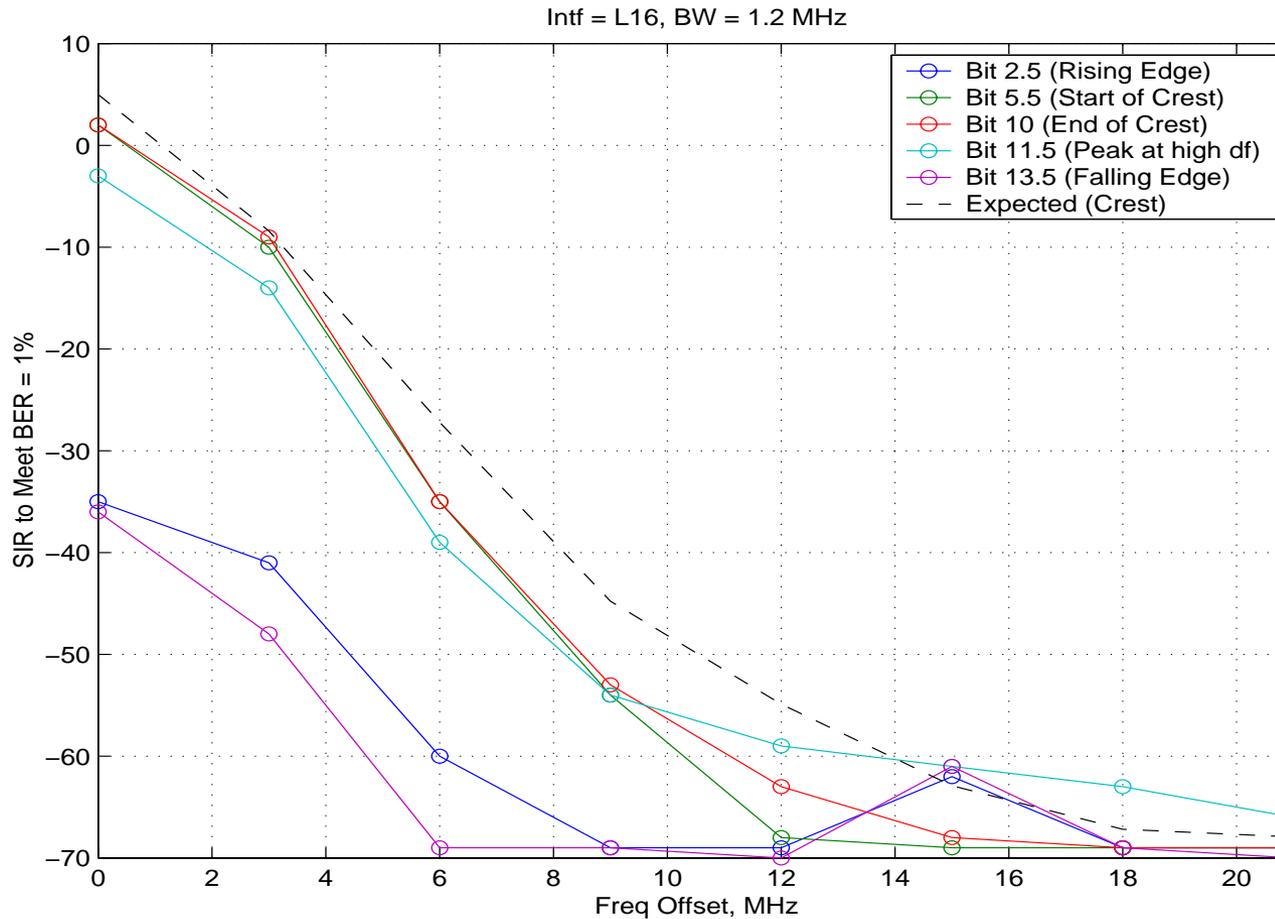

---

## *Required SIR Vs. $\Delta$ freq Plots for Link 16 Interference*

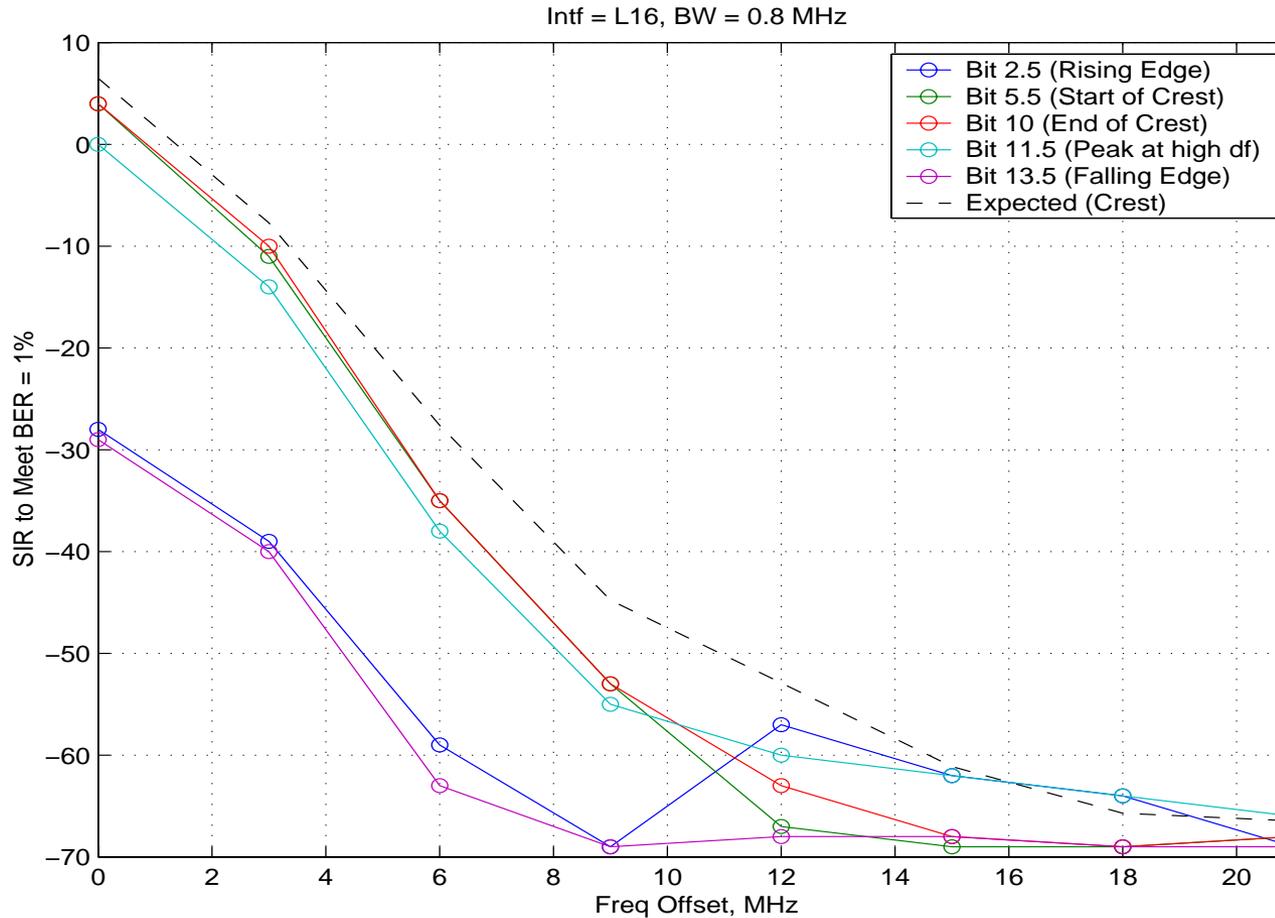

(SIR required to meet BER  $\leq 1\%$  at selected  
time values)

# SIR Required to Meet BER $\leq 1\%$

## BW = 1.2 MHz

# SIR Required to Meet BER $\leq 1\%$ BW = 0.8 MHz

# *BER Observations for Link 16 Interference*

---

- BER vs. SIR curves are parallel
  - Permits simpler modeling of impact than for DME
- Link 16 pulses are longer but less damaging per bit than assumed
  - Overall impact likely close to that originally modeled
  - “Pulse stretching” of a few  $\mu$ secs beyond the modeled 7- $\mu$ sec length occurs for SIRs as high as  $-20$  dB
    - Longer for lower SIRs
    - A  $\sim 7.5$ - $\mu$ sec echo, down 40-45 dB (similar to DME data) can stretch pulses to 17  $\mu$ sec at SIRs of  $-50$  dB
    - 0.8 MHz BW only very slightly worse than 1.2 MHz BW
  - BER impact during central pulse 2-10 dB less than originally modeled (based on Gaussian noise)
    - Reasonable, given that Link 16 is 5 Mchip/sec MSK, not Gaussian noise
    - Two filter BW's about the same
- BERs above 50% were not observed

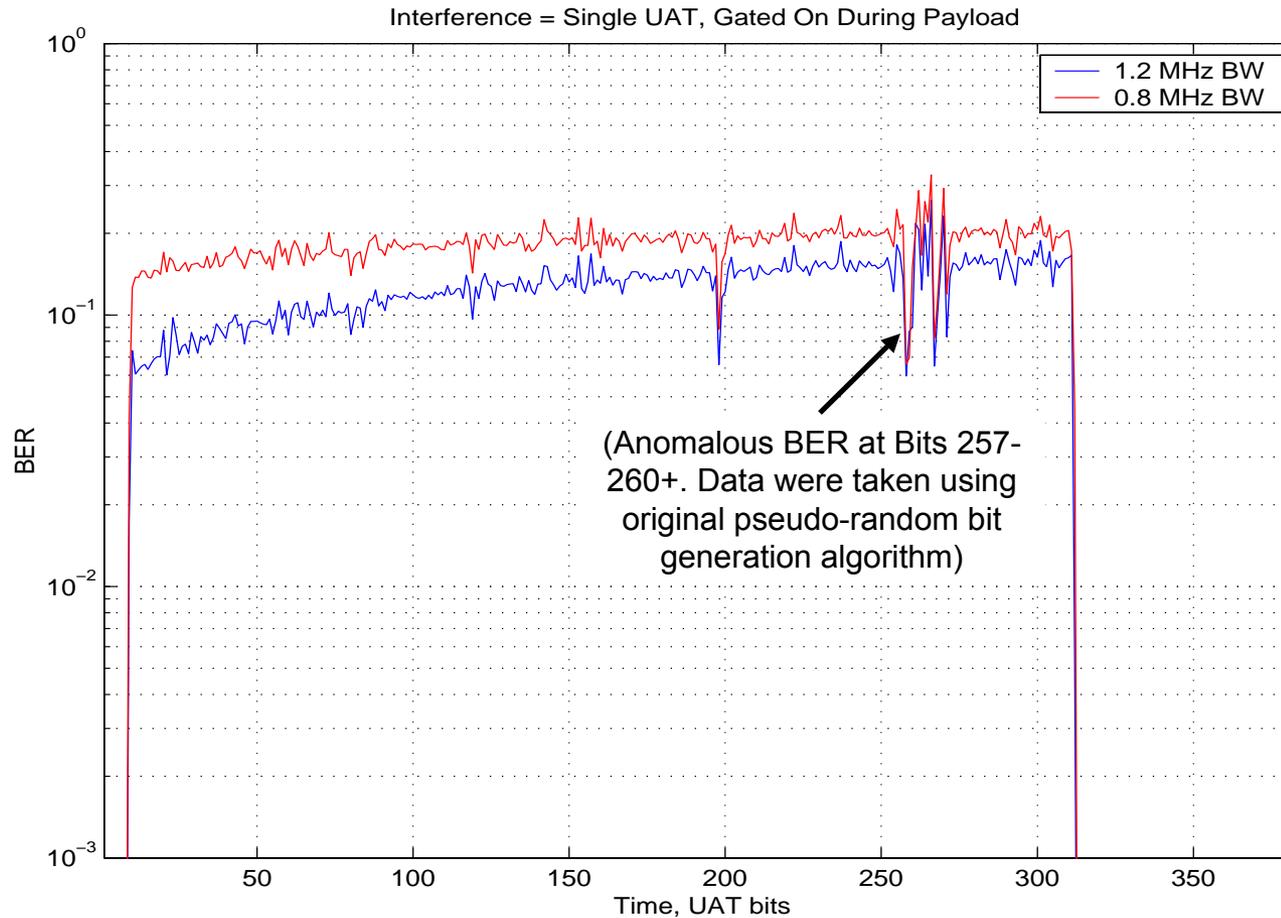

---

***Interference =  
Single UAT + White Gaussian Noise (WGN)***

# *UAT+WGN Tests— Differences From DME and Link 16 Tests*

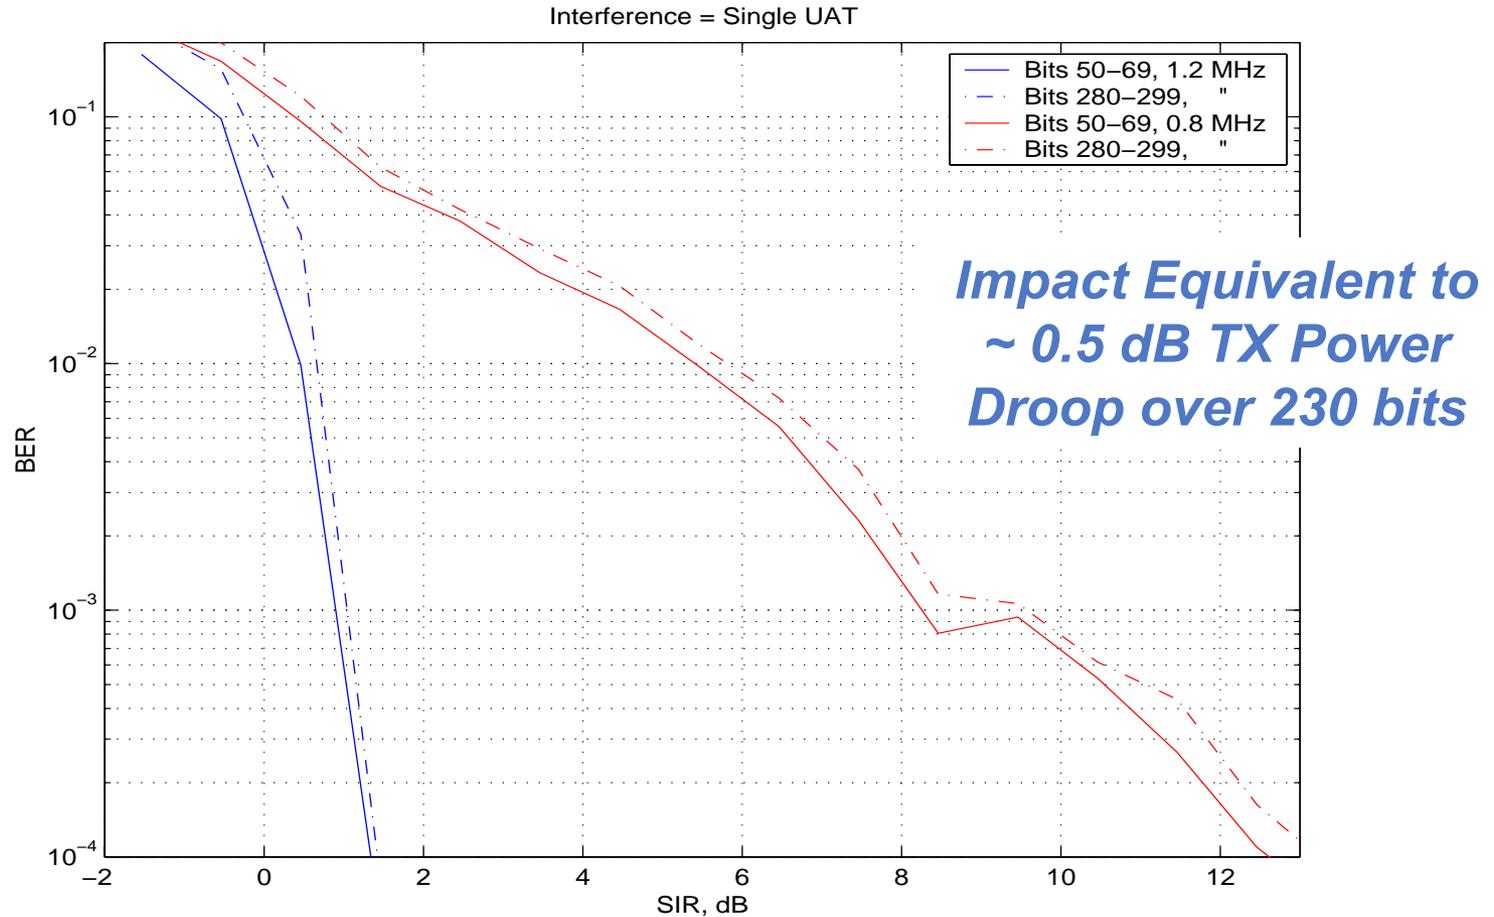

- Need to vary  $INR = \text{UAT Interference} / \text{WGN Ratio}$  for mixed UAT + WGN environments
  - Tested at  $-\infty$  (no UAT),  $-6$ ,  $0$ ,  $+6$ ,  $+8$ ,  $+18$ ,  $\sim +70$  dB (no added WGN)
- For WGN, SNR values need to include specification of measurement bandwidth
  - Use 1 MHz
- Need to gate interference off at message end to screen out mis-correlated messages
  - Use bit positions #16 through #208 of payload for BER computations
- No time profiles computed
  - BERs at all valid bit positions averaged together
  - Discovered BER isn't time-independent
    - Affected previous data as well, but wasn't as noticeable
    - Impact can be ignored

# Rising BER Observed During Single UAT Interference

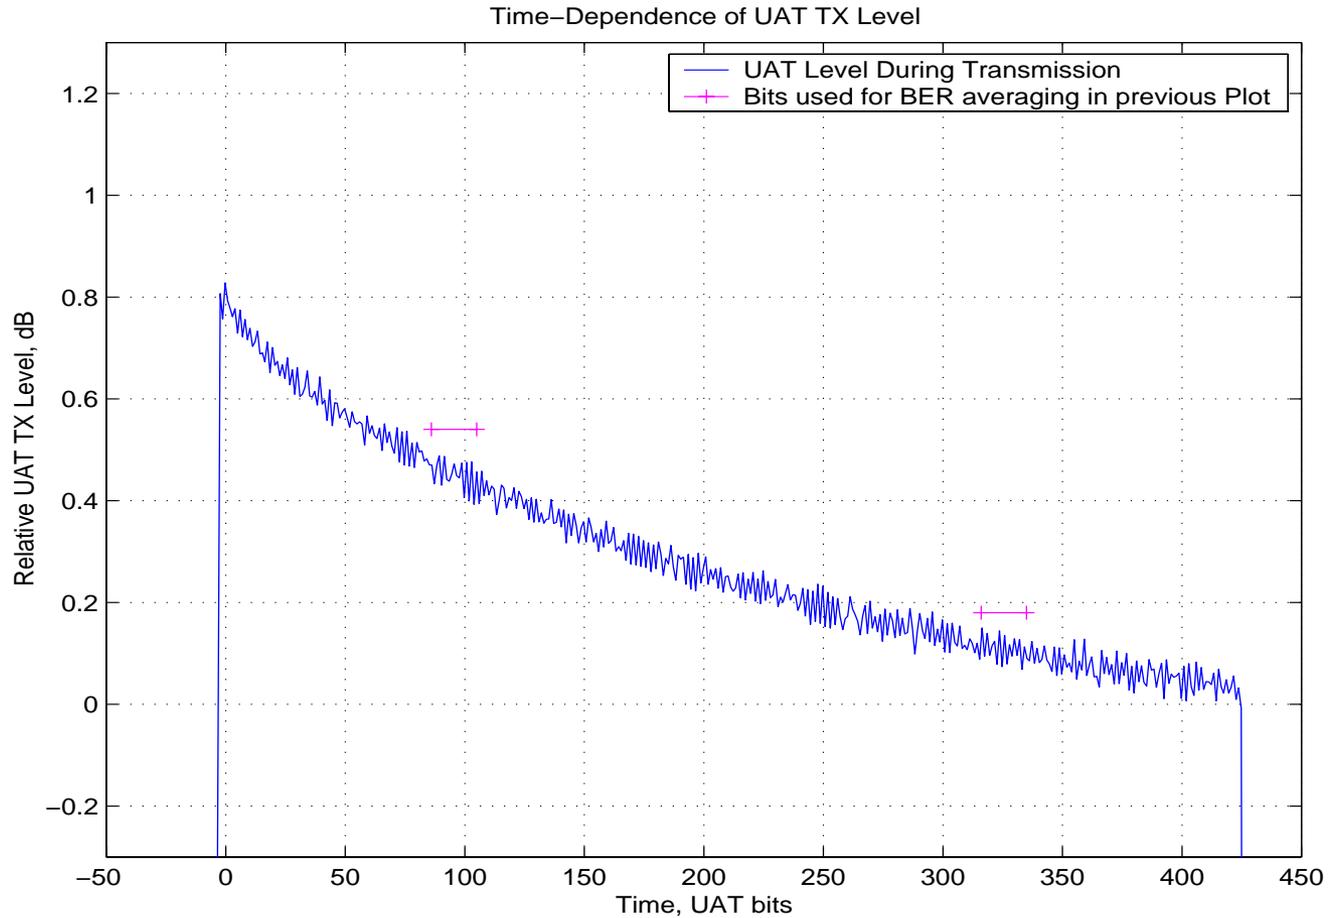

# Consistent with Droop in TX Power Over Message

(In hindsight, effect also present for DME & Link 16 Interference & at all SIRs)

# Confirmation of Hypothesized TX Power Droop

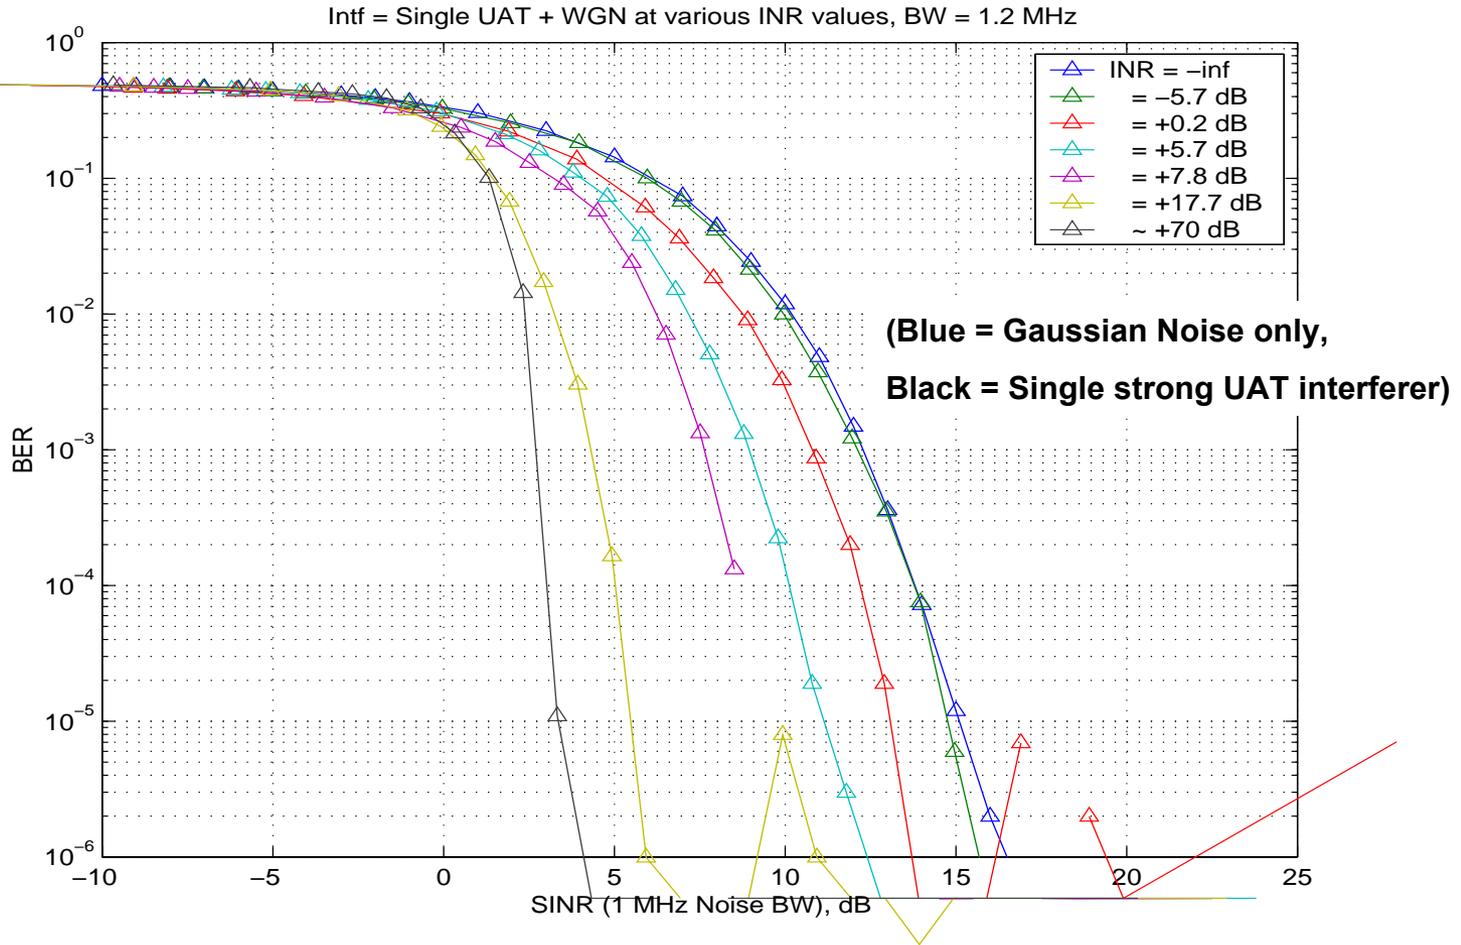

---

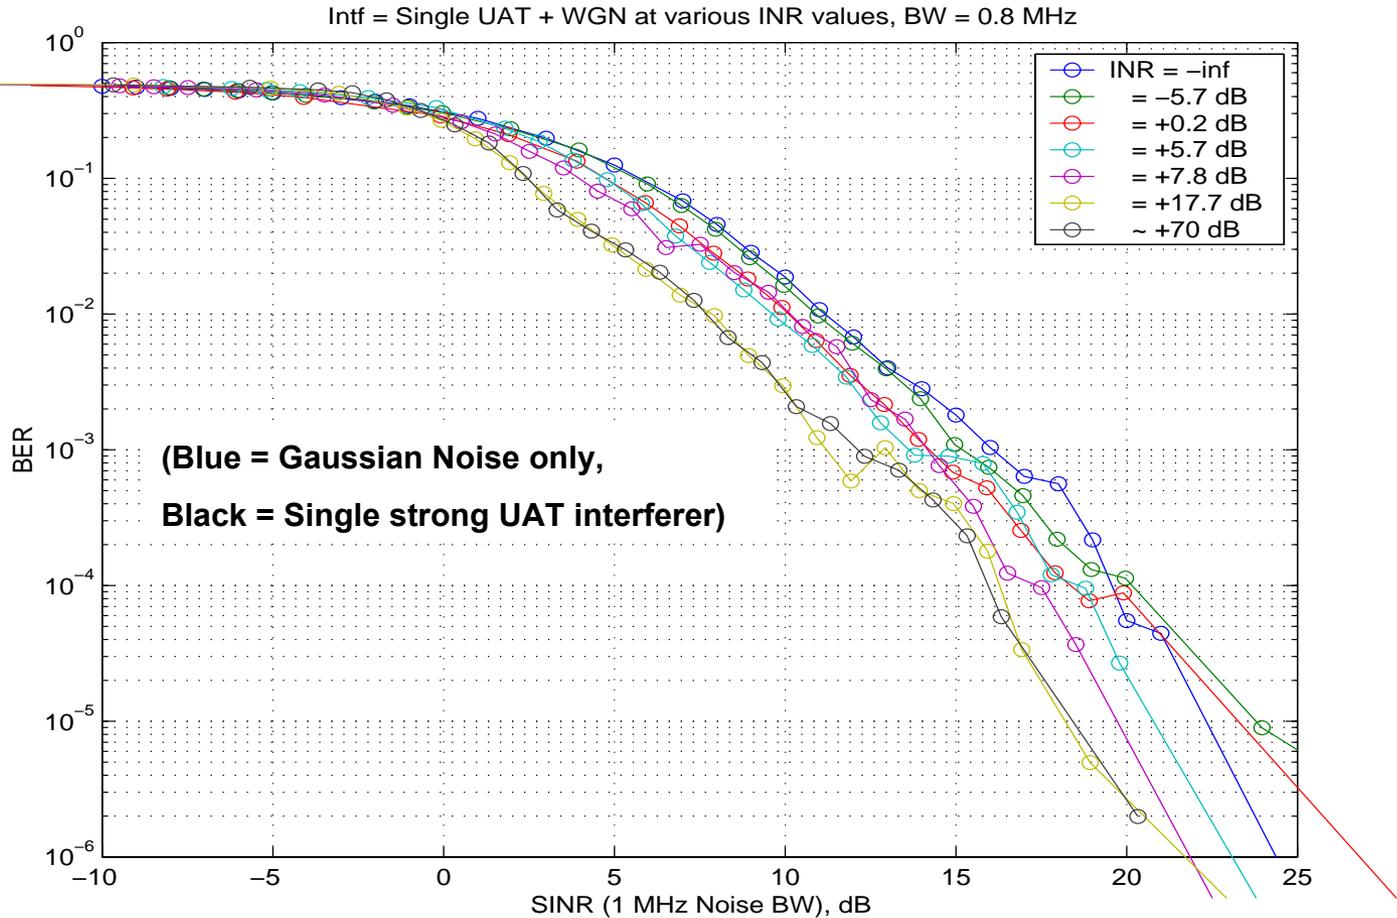

## *BER Vs. SINR Plots for Interference = Single UAT + WGN*

- Summarizes all measured Single-UAT data
  - For each BW (0.8 or 1.2 MHz)
  - Averaged over all interfered bits within a UAT message

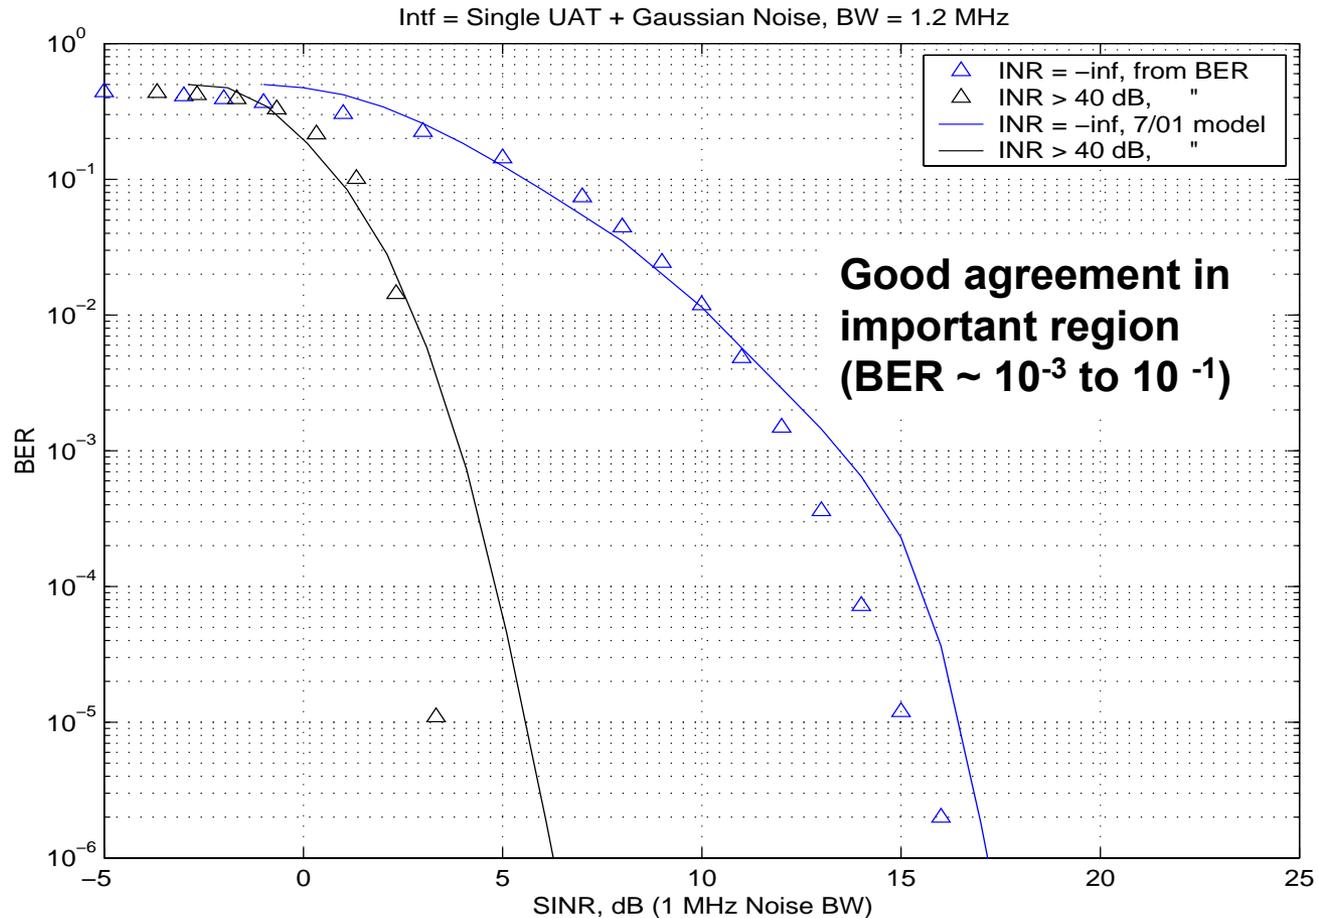

# Interference = Single UAT + WGN, BW = 1.2 MHz

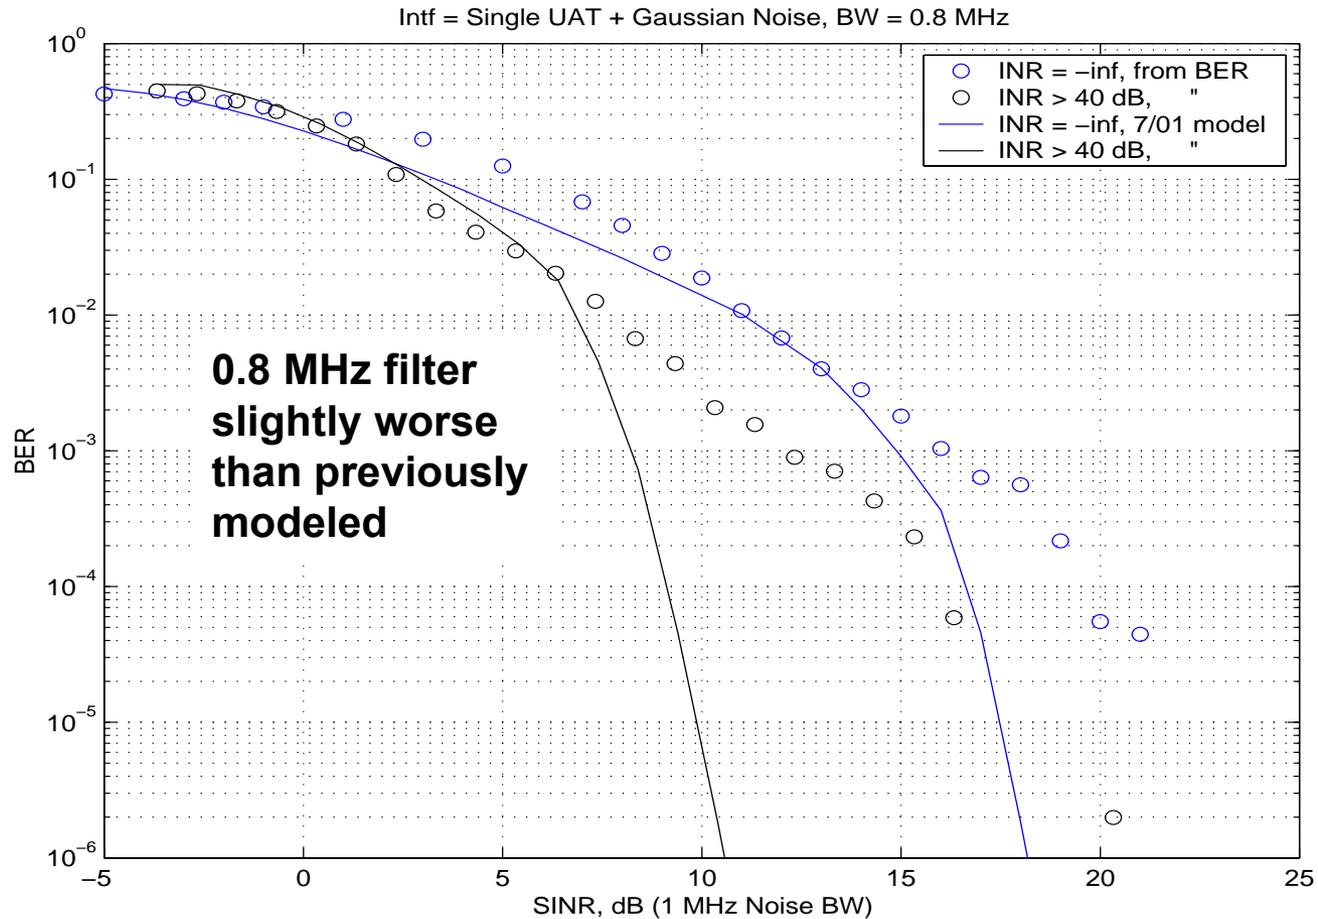

# Interference = Single UAT + WGN, BW = 0.8 MHz

# Comparison of Measured BER with Previous Model (Based on UPS-AT MER Measurements)– 1.2 MHz BW

# Comparison of Measured BER with Previous Model (Based on UPS-AT MER Measurements)– 0.8 MHz BW

# *BER Observations for Single UAT + WGN Interference*

---

- Measured BER are close to previous model (based on MER measurements)
  - Performance of 0.8 MHz BW slightly worse
- UAT interference has very similar impact on 0.8 MHz filter as WGN
  - Nearly the same for the same power in a 2 MHz BW
  - Expected for heavy Inter-Symbol Interference

---

# *Status*

# Performance Modeling With Collected BER Data

---

- Collected BER data can be inserted directly into the multi-aircraft network simulation
  - For every DME or Link 16 reception event (SIR and start time), a time profile of BERs for the following bits is provided
  - For single UAT interference, the BER is assumed constant during interference duration
  - For multiple simultaneous interferers at comparable levels:
    - Measured data is used for common situations (receiver noise and several UAT interferers)
    - Current approach is to assume independent bit errors for less likely situations (DME+UAT, Link 16+UAT, DME+Link 16, etc. ):
$$BER_{12} = BER_1 + BER_2 - 2*BER_1*BER_2$$
      - This approach can be expected to slightly underestimate errors in these infrequent cases

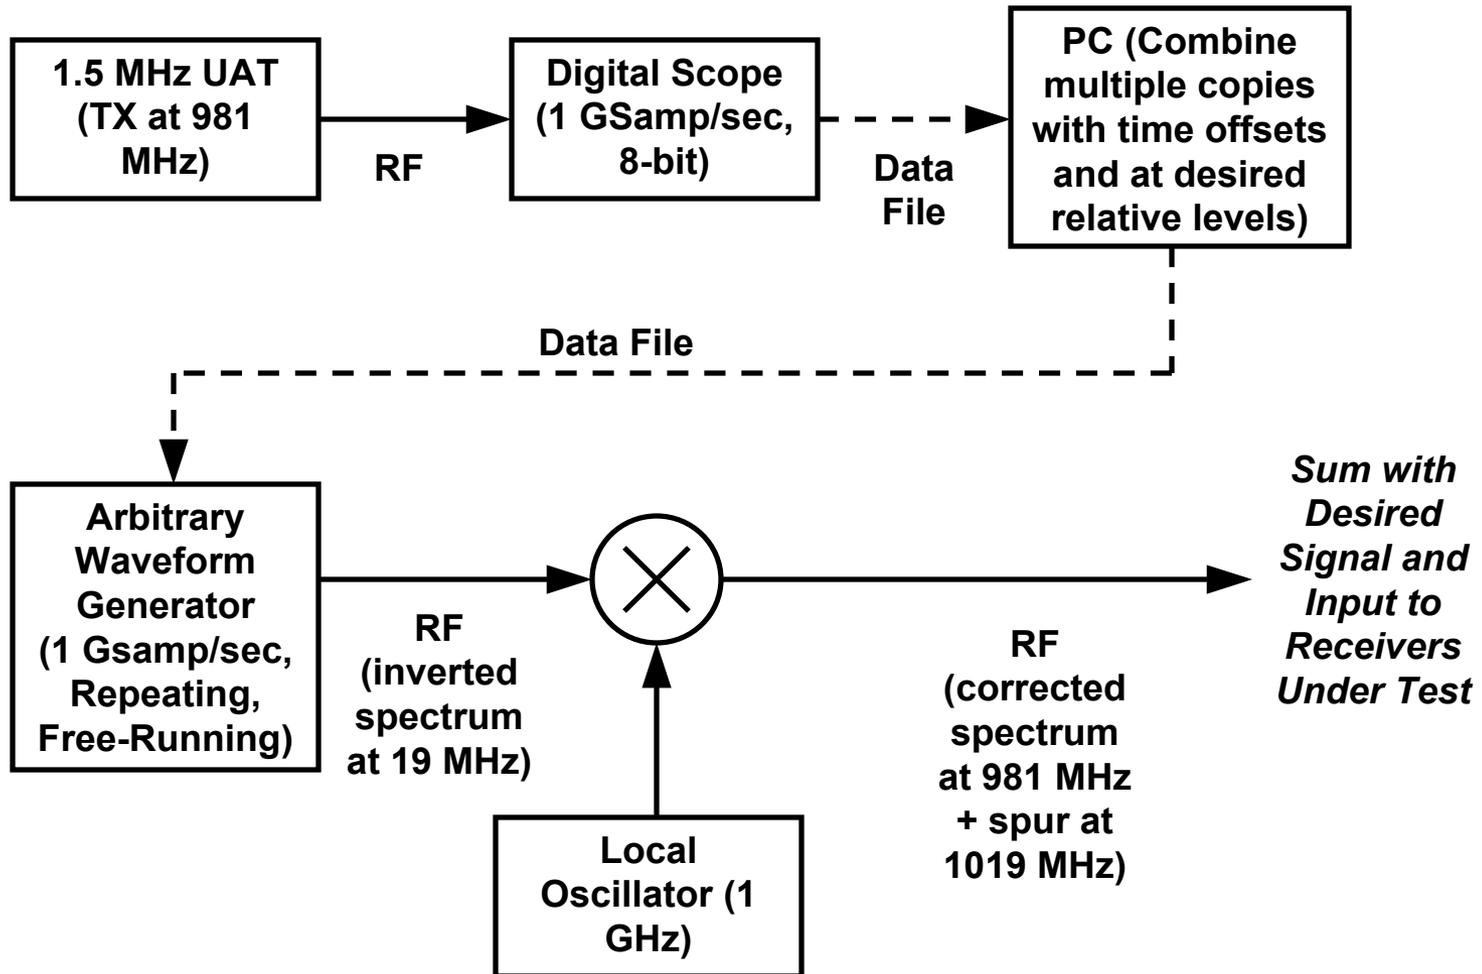

# *BER Test Status*

---

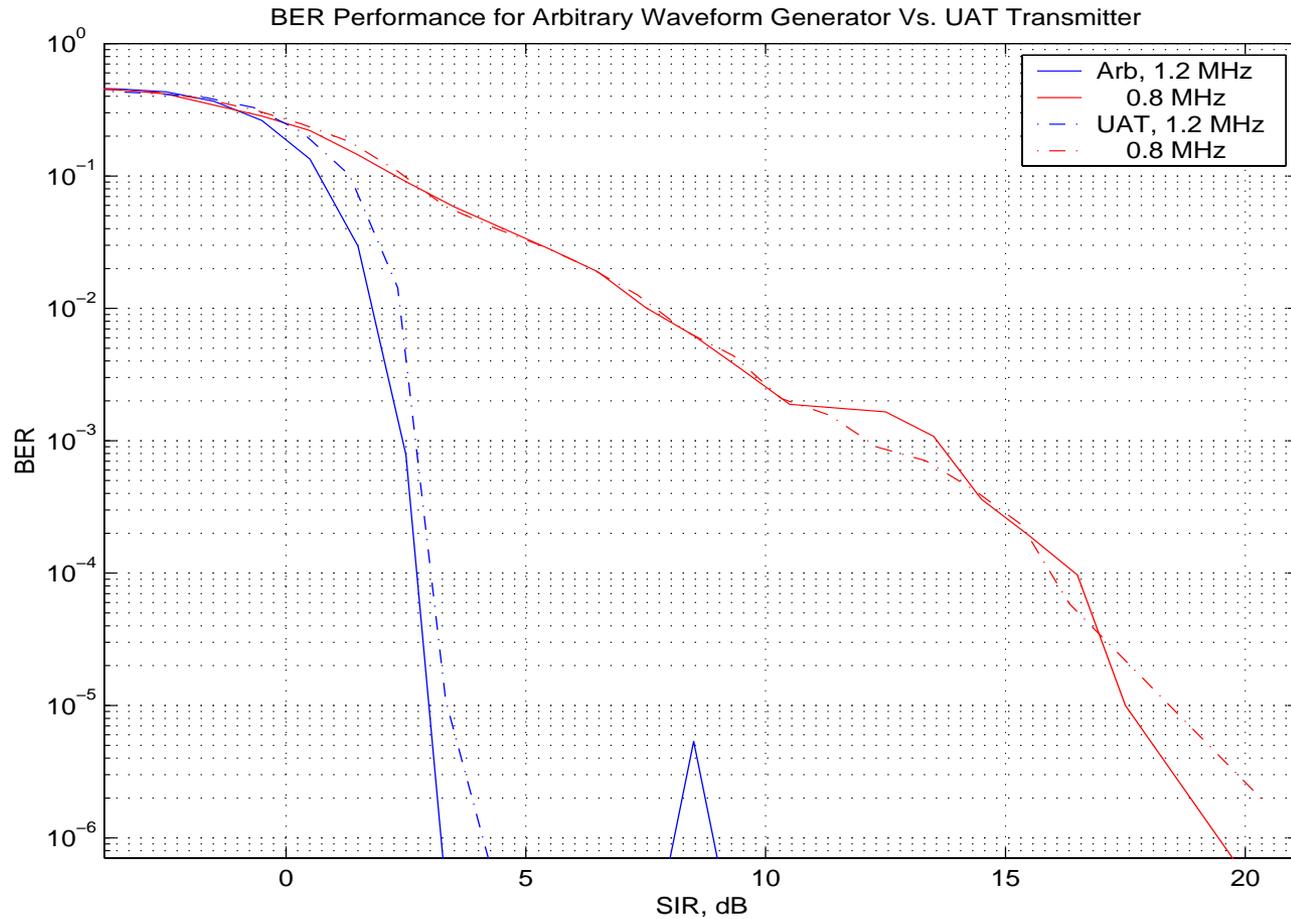

- DME
  - Tests completed
  - Receiver model completed
  - Included in latest multi-aircraft network simulation results
- Link 16
  - Tests completed
  - Receiver model completed
- Single UAT and/or Gaussian Noise
  - Tests completed
- Multi-UAT + Gaussian Noise
  - Initial tests planned for completion by 10 December

# Near-Term Multi-UAT Test Approach

Alternative to multiple TX units or FAA-TC RF UAT Msg. Generator
